1 The ordered sound-change sequence

1.1 Scope and orientation

The sequence begins with early West Germanic consonant and vowel changes and ends with Old English r-metathesis.

Rhotacism, brightening, breaking, umlaut, and apocope alternate with narrowly conditioned changes whose relative order rests on particular witness words.

The evidence ranges from broadly attested sound laws to lexical constraints that establish only one chronological boundary.

1.2 Numbering note

SC numbers remain the established legacy identifiers. The Version 1 book presents the changes in historical chapter order, which differs from the computational cascade order for several rules.

SC038, SC062, and SC084 mark technical or prosodic stages rather than sound changes; SC077 is unused.

2 Chapter 1. From Proto-Germanic to Proto-Northwest Germanic

2.1 Historical interval

This chapter covers developments that took place within the Proto-Germanic period, from the inherited consonant system to the first changes that separate the Northwest Germanic line from the rest of the Germanic family.

The reconstruction labelled Proto-Germanic here is the common ancestor of Gothic, North Germanic, and West Germanic, reconstructed through the classical comparative method from attested descendant languages. The label Proto-Northwest Germanic designates the hypothetical node linking the ancestors of North Germanic (Old Norse and its relatives) and West Germanic (Old English, Old High German, Old Saxon, and Old Frisian among others), to the exclusion of Gothic and the other East Germanic varieties.

2.2 What this chapter contains

Chapter 1 contains one reader-facing sound-change section: the Proto-Germanic loss of a nasal before **x* (SC103 PGmcNasalLossBeforeX), with compensatory lengthening and nasalization of the preceding vowel. Its results are shared by every daughter language, Gothic included, so the change belongs to Proto-Germanic itself and precedes every Northwest Germanic and West Germanic development treated in the chapters that follow (Campbell 1959, 44, §119; Fulk 2018, 55, §4.1; Ringe 2017, 149–50, §3.2.7).

Another historically Proto-Germanic rule, the positional allophony of Proto-Germanic **b* (SC049 PGmcBAllophony), executes late in the computational cascade because the alternation interacts with environments shaped by intermediate rule applications; its section therefore appears in Chapter 4, where the divergence between cascade placement and historical stage is noted explicitly.

One other historically Proto-Germanic change, Gm-simplification (SC002 PGmcGmSimplification), is documented in the book-entry plan and its literature dossier confirms the source base is narrow (two lexical families: **draugma*- ‘dream’ and **taugma*- ‘team’; (Kroonen 2013, 101, 511)). A reader-facing section for SC002 awaits a stronger explanatory source base and is not yet assembled in the reader-facing sequence.

2.3 Scope and genealogical context

Changes in this chapter are pan-Germanic in scope: they apply to ancestral forms that feed both the North Germanic and West Germanic descendants, or they represent internal Proto-Germanic processes visible across the Germanic family.

The boundary between Proto-Germanic and Proto-Northwest Germanic is not sharp in the textbook literature. Ringe and Taylor treat many of the traditionally “Proto-Germanic” changes as part of a shared innovation package that is diagnostically older than North–West Germanic divergence but not necessarily earlier than the separation of the East Germanic line (Ringe and Taylor 2014, 1–30). For book purposes, the distinction matters primarily because it separates the features inherited uniformly from all Germanic from those shared selectively by North and West Germanic to the exclusion of Gothic.

2.4 A note on the rule names

The CAPR rules implemented in this chapter carry names beginning with PGmc. Those names are intended as stable internal identifiers, not as claims about the precise historical stage of every rule so labelled. A rule named PGmcX may in some cases be a later development that affects only the West Germanic or Northwest Germanic branch; the chapter assignment in this staging map takes priority over the rule-name prefix for historical organization purposes.

3 Proto-Germanic loss of a nasal before *x

3.1 Historical discussion

The oldest change treated in this book is common to the whole family. In the group *-nx- the nasal consonant was lost, the preceding vowel was lengthened in compensation, and that lengthened vowel was nasalized. Its results are shared by every daughter language: Gothic *þeiħan* ‘thrive’, *brāhta* ‘brought’, *þūhta* ‘seemed’ stand beside Old High German *dīħan* ‘thrive’, *brāhta*, *fūht* ‘damp’ and Old English *þēon* ‘thrive’, *brōhte* ‘brought’, *þūhte* ‘seemed’, *fūht* ‘damp’ (Campbell 1959, 44, §119; Fulk 2018, 55, §4.1; Ringe 2017, 149–50, §3.2.7). Because no daughter keeps the nasal, the change belongs to Proto-Germanic itself, and it precedes every Northwest Germanic, West Germanic, North Sea Germanic and Anglo-Frisian development described in the chapters that follow.

Only *a, *i and *u occur in this position. Germanic had already raised *e to *i and *o to *u before a nasal followed by a consonant, so the mid vowels are absent from the input (Fulk 2018, 55, §4.1).

The vowel that the change creates is long and nasalized, and it is not yet rounded. Fulk emphasizes that the lengthened vowels remained nasalized for a considerable time, well past the close of the Northwest Germanic period, since the nasalized low vowel produced in this way went on to develop to *ō* in Anglo-Frisian and did not fall together with the Old English *ā* that came from *ai (Fulk 2018, 55, §4.1). The comparative material makes the same point directly: Gothic, Old Norse, Old High German and Old Saxon all reflect the Proto-Germanic nasalized low vowel as unrounded *ā*, and only Old English and Old Frisian show *ō* (Campbell 1959, 44, §119; Fulk 2018, 72, §4.11). Ringe describes Proto-Germanic *hanhanq as *[xāxanq] and observes that its low vowel was rounded, along with the other nasalized low vowels, in the northernmost West Germanic dialects (Ringe 2017, 149–50, §3.2.7). That rounding is a separate and much later change, and it is treated in the chapter on the rounding of the long nasalized low vowel.

3.2 SC103. Proto-Germanic nasal loss before x (PGmcNasalLossBeforeX)

```
define PGmcNasalLossBeforeX [  
  {*a} -> {*ā} || _ EnglishStarNasal {*x},  
  {*i} -> {*ī} || _ EnglishStarNasal {*x},  
  {*u} -> {*ū} || _ EnglishStarNasal {*x},  
  {*á} -> {*ā} || _ EnglishStarNasal {*x},  
  {*í} -> {*ī} || _ EnglishStarNasal {*x},  
  {*ú} -> {*ū} || _ EnglishStarNasal {*x}  
] .o. [  
  EnglishStarNasal -> 0 || _ {*x}  
];
```

The rule performs the three parts of the change together: it lengthens the vowel, it marks the lengthened low vowel as nasalized, and it then removes the conditioning nasal. The low vowel is written *ā and the high vowels are written *ī and *ū, because the nasality of the high vowels has no further consequence: they go on to develop exactly as the inherited long *ī and *ū do (Campbell 1959, 47, §121). The nasality of the low vowel is carried forward because its later fate depends on it.

The corpus witnesses both branches of the rule. The high branch is *fūnxstiz ‘fist’, which becomes *fūixsti ‘fist’ and, after the loss of *x before the cluster in SC028 PNWGmcPreconsonantalXLoss, gives Old English *fȳst* ‘fist’. The long vowel of Old High German *fūst* ‘fist’, Dutch *vuist* and German *Faust* shows that the word belongs here and to no later law (Kroonen 2013, 160). The rule also supplies the *xst cluster on which the loss of *x before a consonant operates, so the two stand in a feeding relation.

The low branch is *θānxte ‘thought’, the preterite of the verb ‘to think’, whose principal parts are reconstructed as *þankijanq ‘to think’, *þanhte ‘thought’, *þanhtaz ‘thought (past participle)’

with the nasal still standing before the fricative (Ringe 2017, 281; 2017, 136). Here the rule yields **θāxtē* ‘thought’, and the nasalized low vowel is later rounded by SC104 EAFNasalizedLowRounding to give Old English *þōhte* ‘thought’. This is the form the handbooks themselves cite for the Anglo-Frisian rounding of the vowel produced here (Fulk 2018, 55, §4.1). It does not enter the loss of **x* before a consonant, in which respect it differs from ‘fist’, so the fricative survives to the surface and the word displays the vowel history alone.

4 Chapter 2. From Proto-Northwest Germanic to Proto-West Germanic

4.1 Historical interval

This chapter covers the sound changes that took place in the proto-language shared by the West Germanic languages — Old English, Old Frisian, Old Saxon, Old High German, and Old Dutch — before the individual languages diverged. The starting reconstruction is Proto-Northwest Germanic (PNWGmc), the hypothetical common ancestor of North Germanic and West Germanic together; the ending reconstruction is Proto-West Germanic (PWGmc), the immediate common ancestor of the West Germanic languages specifically.

4.2 Scope and internal diversity

Changes in this chapter are not all equally pan-West-Germanic in scope. They may be grouped broadly as follows:

Northwest Germanic innovations (shared by both North and West Germanic): innovations in the unstressed vowel system, certain final-syllable vowel changes, and selected consonant cluster simplifications. Changes labelled NWGmc in the CAPR rule names fall here, though rule prefixes are not always reliable guides to historical scope.

Proto-West-Germanic innovations (shared within West Germanic but not in North Germanic): the cluster of morphological and phonological changes that distinguish Old English, Old High German, Old Saxon, and Old Frisian from Old Norse. Changes labelled PWGmc in the CAPR rule names generally fall here. They include early apocope rules, certain consonant assimilations, and the West Germanic gemination of consonants before *j.

4.3 Major changes

The chapter opens with the root-noun nominative *-z loss (SC096), the generalization of ending-less nominatives through the athematic consonant stems, complete before Proto-West Germanic: none of the West Germanic daughters shows any ending in this class (Ringe and Taylor 2014, 118). It is the earliest of the three historically distinct final-*z developments; the other two (SC020 and SC097) open Chapter 3.

The unstressed *ai > *ē development (SC014) represents one of the most pervasive shared NW–West Germanic vowel shifts, turning unstressed endings such as the dative singular and strong-adjective plural to longer vowels. Ringe and Taylor treat this as one of the clearest post-PNWGmc shared developments (Ringe and Taylor 2014, 40–41); Fulk groups it among the North/West-Germanic shared innovations that distinguish the period from Gothic (Fulk 2018, sect. 5.2). The corresponding stressed monophthongization (SC004) belongs later in the cascade and is treated in Chapter 3.

The West Germanic consonant changes of this chapter — j-gemination (SC010), early i-apocope (SC006), coronal-w assimilation (SC008), and related rules — represent the most productive phonological territory for the CAPR derivations. They feed a large proportion of the distinctive consonant clusters of Old English. Handbooks vary in exactly how they group and name these changes (Campbell 1959, sects 404, 406; Hogg 1992a, sect. 4.11).

The nasal spirant corridor (SC026–SC027), treated in Chapter 3 at its cascade position, illustrates a type of change common in historical grammars of the “Ingvaemonic” or “North Sea Germanic” area: nasals disappear before voiceless fricatives, with compensatory vowel lengthening (Campbell 1959, sects 462–463; Hogg 1992a, sects 3.13–3.14). The CAPR model splits this into two ordered steps to make the vowel effect computationally tractable; the book prose explains that split against the handbook tradition, which typically presents the change as a single process.

Chapters in this part of the book follow the executable cascade order, which models the reconstructed chronology itself. Several rules that carry PWGmc labels — final bare-*a loss (SC041), surviving bimoric *ō unrounding (SC042), and Sievers-law syncope (SC050) — execute later in

the cascade and are therefore presented in Chapter 4, where their individual sections discuss their historical stage labels. Conversely, one rule with a West Saxon label, the palatal-glide rule (SC016), is an orthographic rule of the written surface: it executes after the Old English orthography stage and is presented in Chapter 5.

One historically Proto-Germanic change, Gm-simplification (SC002 PGmcGmSimplification), precedes everything in this chapter as a support stage of the cascade. It is documented in the book-entry plan and its literature dossier confirms the source base is narrow (two lexical families: **draugma*- ‘dream’ and **taugma*- ‘team’; (Kroonen 2013, 101, 511)). A reader-facing section for SC002 awaits a stronger explanatory source base and is not yet assembled in the reader-facing sequence.

4.4 A note on source terminology and subgrouping

The literature uses several partly overlapping stage labels for this period:

- Northwest Germanic: the node uniting North and West Germanic.
- Proto-West Germanic: the node uniting only the West Germanic languages.
- North Sea Germanic or Ingvaeonic: a proposed subgroup within West Germanic covering Old English, Old Frisian, and Old Saxon (and sometimes Old Low Franconian), sharing certain innovations over a broader area.
- Anglo-Frisian: a narrower proposed subgroup linking only Old English and Old Frisian.

These labels are not always used consistently across sources. Ringe and Taylor are cautious about reconstructing a discrete Proto-West-Germanic node (Ringe and Taylor 2014, 50–55). Campbell notes that many of the “West Germanic” shared features could alternatively be treated as parallel developments rather than common inheritance (Campbell 1959, sects 1–5).

CAPR uses PWGmc and NWGmc as organizing labels for this chapter without claiming to have settled all questions about West Germanic subgrouping. Changes that appear in the literature under “Ingvaeonic” labels but affect the Old English-to-Proto-Germanic derivation chain are treated here as late expressions of the same West Germanic developmental period unless existing CAPR dossier research specifically argues for Anglo-Frisian or English-specific placement.

4.5 Rule names

The CAPR rules in this chapter carry names beginning with NWGmc or PWGmc. These names are stable internal identifiers. A name beginning with NWGmc does not guarantee that the change is exclusive to Northwest Germanic, and a name beginning with PWGmc does not guarantee that it is absent from North Germanic. The historical analysis in each sound-change section takes priority over the name prefix.

5 Root-noun nominative *-z loss

5.1 Historical discussion

The athematic consonant stems — the “root nouns” of the handbooks — attached the nominative-singular marker directly to a consonant-final root, and the Proto-Germanic outcome of that collision is genuinely uncertain. Ringe gives the consonant-stem nominative ending as zero, *-z, or possibly *-s, and states plainly that the distribution is unrecoverable for monosyllabic stems (Ringe 2017, 306, §4.3.4). His own paradigm tables carry the uncertainty into print: the nominative of ‘foot’ appears as “fōts? (fōs?)”, while ‘mouse’ is plain **mūs*, its expected extra sibilant already absorbed by degemination (Ringe 2017, 149, 313). Ringe and Taylor repeat the same three-way agnosticism — the root-noun nominative “either ended in *-s or *-z, or was ending-less” (Ringe and Taylor 2014, 28, §2.3.1).

The dictionary traditions encode this situation in different notations, and the differences are conventions of citation rather than competing claims of fact. Orel prints morphologically explicit nominatives with final -z across the whole class: **bōkz* ‘book’, **gansz* ‘goose’, **lūsz* ‘louse’ (Orel

2003, 52, 126, 252). Kroonen cites the same words as bare stems or endingless forms, **bōk-* and **gans-* (Kroonen 2013, 71–72, 168–69), and Kluge/Seebold print a third variant with voiceless *-s*, as in **bōks* ‘Buch’ (Kluge 2011, 158). Bammesberger shows why the marker is nonetheless real: for voiced-final stems the overt nominative **-z* is positively reconstructible — **burgz* (Gothic *baúrgs*), **frijōndz* (Gothic *frijonds*) — even though **fōt-z* is “phonotaktisch kaum denkbar”, and in West Germanic the ending simply “fiel es ab” (Bammesberger 1990, 190–92, §8.2.3.1). CAPR retains Orel’s morphologically explicit forms as its inputs precisely because they record the inflectional marker whose fate this rule describes.

The three focal words are only superficially parallel. The root-final *s* of ‘louse’ is itself an extension of **luw-* on the model of ‘mouse’ (Bammesberger 1990, 195, §8.3). For ‘goose’, Szemerényi’s lengthening would give a Proto-Indo-European nominative **ǵʰanss* > **ǵʰān*, after which the Proto-Germanic nominative was rebuilt with a final voiced sibilant, **ganz*, reanalyzed within the paradigm (Bammesberger 1990, 196, §8.3; Kroonen 2013, 168–69). ‘Book’ preserves a plain obstruent-final root. What unites them is not a single phonetic history but membership in a paradigm class that generalized the endingless nominative.

The branch evidence dates and localizes that generalization. Gothic keeps its sibilant throughout the class (*baúrgs*, *nahts*, *reiks*) (Fulk 2018, 165–66, §§7.26–7.27). Old Norse redistributes the ending morphologically: masculine root nouns keep *-r* (*fótr*), feminines are endingless (*nótt*, *geit*), while the vocalic-stem feminines *kýr*, *sýr*, *ær* retain *-r* from **-z* with R-umlaut (Fulk 2018, 167, §7.28; Bammesberger 1990, 192–93). West Germanic alone is uniform: there was “no ending in PWGmc, as none of the daughters exhibits any” (Ringe and Taylor 2014, 118, §3.4). Fulk supplies the mechanism: Szemerényi’s law removed the nominative sibilant after sonorant-final stems, and endinglessness then spread analogically through the class (Fulk 2018, 143, §7.2). The development is therefore best understood as a morphological generalization enacted differently in each branch — absolute in West Germanic, consonant- and gender-conditioned in North Germanic, absent in Gothic — rather than as one exceptionless sound law.

This change is distinct from the two later final-**z* developments. It was complete before Proto-West Germanic, whereas the loss of **-z* in unstressed syllables (SC020 EAffFinalZDeletion) is itself a Proto-West Germanic change: polysyllabic consonant-stem nominatives such as **fadurz* ‘father’ — and, in this corpus, **frijōndz* ‘friend’, **melukz* ‘milk’, and **mēnōþz* ‘month’ — kept their ending into Proto-West Germanic and lost it there in an unstressed syllable (Ringe and Taylor 2014, 44–45, §3.1.1). The still later northern loss of **-z* in stressed monosyllables (SC097 MonosyllabicFinalZLoss) affects vowel-final monosyllables like **hwaz* and does not touch the consonant-final root nouns at all, whose ending was gone long before.

5.2 SC096. Root-noun nominative **-z* loss (RootNounNomZLoss)

```
define RootNounNomZLoss [{*z} -> 0 ||
  .#. [EnglishStarConsonant | EnglishPalatalConsonant]*
    EnglishStarVocalic+
    [EnglishStarConsonant | EnglishPalatalConsonant]+ _ .#.];
```

The rule deletes word-final **z* after a consonant in a monosyllable. Three claims of different kinds meet here and must be kept apart. The historical claim is morphological: the nominative-singular ending was lost in the athematic root-noun class, so that this one paradigm cell came to lack its marker — a development complete before Proto-West Germanic (Ringe and Taylor 2014, 118, §3.4). The lexical claim belongs to the dictionaries: Orel’s citation forms, which supply the corpus inputs, print that marker explicitly as *-z* in **bōkz*, **flauxz*, **gansz*, and **lūsz* (Orel 2003, 52, 105, 126, 252). The executable statement is neither of these but a computational proxy for them: ‘delete word-final **z* after a consonant in a monosyllable’. It is not proposed as a Proto-Germanic sound law; it earns its place only because every form the corpus submits to the morphological development is a consonant-final monosyllable, so the narrow phonological statement covers the class exactly. Four corpus derivations witness the rule, each yielding its expected Old English outcome: PGmc **bōkz* ‘book’ yields OE *bōc* ‘book’, **gánsz* ‘goose’ yields *gōs* ‘goose’, **lūsz* ‘louse’ yields *lūs* ‘louse’, and **fláuxz* ‘flea’ yields *flēah* ‘flea’. Should the corpus ever acquire a consonant-final monosyllable in **-z* that is not a root-noun nominative, the proxy and the morphology would

come apart, and the rule would need to be re-scoped; the project’s regression tests pin the firing population to exactly these four words so that any fifth firing forces that adjudication rather than passing silently.

The rule applies at the head of the English line, before SC009 PWGmcIjContraction. That ordering is fixed by the identity of the process rather than by a wrong form: contraction turns the polysyllabic **frīōndz* ‘friend’ into a monosyllable, and if the root-noun rule applied after contraction it would capture **friundz* — yet the ending of ‘friend’ survived into Proto-West Germanic and fell in an unstressed syllable, the change described under SC020 EAffFinalZDeletion (Ringe and Taylor 2014, 44–45, §3.1.1). Because both rules delete the same segment, moving this rule later changes no Old English output; the early placement keeps the derivation of ‘friend’ aligned with the historical account rather than with an accident of the cascade.

Negative controls behave as the morphology predicts. Stressed monosyllables whose **z* follows a vowel — the domain of the later northern change — do not meet the post-consonantal environment. Medial **z* is untouched and remains available for rhotacism (SC003 EAFRhotacism): PGmc **déuzq* ‘deer’ still yields OE *dēor* ‘deer’ with its rhotacized medial consonant.

6 Early unstressed vowel changes

6.1 Historical discussion

The first change monophthongizes unstressed **ai*; the second carries early unstressed front-vowel leveling farther in forms such as *weorold* ‘world’. Both have a diagnostic later boundary in the dataset.

6.2 Historical discussion of unstressed **ai* monophthongization

Ringe and Taylor describe the broad Northwest Germanic reduction of unstressed **ai* to a long mid vowel that merges with unstressed **e*, in final and nonfinal syllables alike (Ringe and Taylor 2014, 37–41). Two dative-singular endings in the dataset, span **spánnai* ‘span’ and meed **mízdai* ‘meed’, carry the change. The stressed development of **ái* to **ā* is treated separately as SC004 EAFaiMonophthongization.

6.3 SC014. Monophthongization of unstressed **ai* (PNWGmcUnstressedAiMonophthongization)

```
define PNWGmcUnstressedAiMonophthongization [  
  {*ai} -> {*ē}  
];
```

The dative-singular endings span **spánnai* ‘span’ and meed **mízdai* ‘meed’ carry this change; both give a final **ē*. If SC014 PNWGmcUnstressedAiMonophthongization is delayed until after SC072 OEUnstressedLongVowelShortening, the **ē* is no longer present for shortening, so PGmc **spánnai* ‘span’ yields *†spannē* rather than expected OE *spanne* ‘span’. This shows that SC014 PNWGmcUnstressedAiMonophthongization must come before SC072 OEUnstressedLongVowelShortening in the modeled sequence.

Ringe and Taylor’s merger of unstressed **ai* with long mid **ē* establishes the historical development, in final and nonfinal syllables alike. The stressed development of **ái* to **ā* is a separate and later change; see SC004 EAFaiMonophthongization.

6.4 Historical discussion of early unstressed front-vowel leveling

Campbell treats the merger of unstressed front vowels directly and also records the variation of *weorold* ‘world’ and *weoruld* ‘world’ (Campbell 1959, 141–42, 154–55). These forms supply SC015 PNWGmcILowering with a firmer lexical basis than the preceding change.

6.5 SC015. Leveling of early unstressed front vowels (PNWGmcILowering)

```
define PNWGmcILowering [  
  {*i} -> {*e}  
  || .#. EnglishStarNonVelarConsonant* _  
    EnglishStarCoronal+ EnglishStarNonHighVowel,  
  {*í} -> {*é}  
  || .#. EnglishStarNonVelarConsonant* _  
    EnglishStarCoronal+ EnglishStarNonHighVowel  
];
```

The *weorold* ‘world’ and *weoruld* ‘world’ variants turn the general source claim into an ordering test. If SC015 PNWGmcILowering is delayed until after SC036 OEInterStressRaising, PGmc **wír-àldu* ‘world’ yields *†wuruld* rather than expected OE *weorold* ‘world’; earlier movement changes no output.

The derivation thus fixes front-vowel leveling before interstress raising while leaving its earlier boundary open.

SC016 OEWSPalatalGlide and SC017 PNWGmcULowering follow with a more tightly constrained local chronology.

7 Unstressed **a*-raising before final **m*

7.1 Historical discussion

Campbell notes that unstressed *u* is especially well preserved before *m*, with dat.pl. *-um* and related endings as the clearest evidence (Campbell 1959, 156, §373). Fulk likewise includes the development of early unstressed **o* to *u* before *m* among the similarities shared by North and West Germanic (Fulk 2018, 16, §5.2).

I restrict the change to unstressed vowels in inflectional material because the strongest evidence concerns noninitial unstressed material before final **m*. Final **m* conditions the raising.

7.2 SC005. Unstressed **a*-raising before final **m* (PNWGmcAToUBeforeM)

```
define PNWGmcAToUBeforeM [  
  {*a} -> {*u} || EnglishStarVocalic EnglishStarConsonant+ _ {*m} ({*i})?  
  ↪ ({*z})? .#.  
];
```

Here the witness word and the comparative evidence serve different purposes. If raising is delayed until after SC017 PNWGmcULowering, PGmc **skúldramiz* ‘shoulders’ yields *†scoldrum* rather than expected OE *sculdrum* ‘shoulders’; earlier placements converge on the expected output. The scope of the change is established by inflectional evidence across multiple paradigm types: a-stem dative plural ON *dǫgum* ‘days’, OE *dagum* ‘days’, OS *dagun* ‘days’, OHG *tagum* ‘days’, beside Gothic *dagam* ‘days’; strong-adjective dative singular ON *góðum* ‘good’, OE *gōdum* ‘good’, OS *gōdum* ‘good’, beside Gothic *godamma* ‘good’ (OS also shows variant forms *gōdumu* and *-un*); and first-plural present ON *berum* ‘we carry’, OHG *berumēs* ‘we carry’, beside Gothic *baíram* ‘we carry’. Across these sets, North/West Germanic shows unstressed *-um* where Gothic preserves *-am*. The derivation of *sculdrum* ‘shoulders’ supplies a CAPR ordering witness for the relative chronology, but the cognate set for ‘shoulder’ does not contribute comparative evidence for the rule’s historical scope.

8 Northwest Germanic lowering of long $\bar{e}$

8.1 Historical discussion

Proto-Germanic $*\bar{e}_1$ (the long mid vowel of PIE origin, as against the later $*\bar{e}_2$) split East Germanic from the rest of the family. Gothic keeps a mid vowel, written ηe , in *gadēps* ‘deed’, *slēpan* ‘to sleep’, *mēna* ‘moon’, and *jēr* ‘year’, while Norse and all of West Germanic show a low vowel, as in Old Norse *ráða* ‘to consider, to advise’, *láta* ‘to let go, to allow’, *ár* ‘year’, *nál* ‘needle’, Old High German *tāt* ‘deed’, *slāfan* ‘to sleep’, *jār* ‘year’, *māno* ‘moon’, Old Saxon *dād* ‘deed’, *slāpan* ‘to sleep’, *jār*. Ringe and Taylor assemble the comparative set and reconstruct a Northwest Germanic sound change $*\bar{e}_1 > *\bar{a}$ (Ringe and Taylor 2014, 11–13). The change is directly dated by the earliest epigraphy. The Early Runic accusative *mākija* ‘sword’ (beside Gothic *mēkeis* ‘sword’) already shows ηa in the second half of the second century AD (Ringe and Taylor 2014, 12), and the a-rune likewise writes the stressed reflex in the Opedal stone’s *swestar* ‘sister’ (Stiles 2017, 4). Loanwords borrowed into Sami from early Proto-Scandinavian point the same way. Lid showed that the root vowel of Sami *mānno* ‘moon’, Proto-Germanic $*\bar{e}$ as in Gothic *mēna*, “had gone over to $\bar{a}$ before the word was borrowed into Sami”, and adduced the parallel Sami *saððo* ‘bran’ beside Proto-Nordic $*sāððo$ from $*sēððo$ -, Old Norse *sáð* ‘bran’ (Lid 1952, 238). This is Sami borrowing from Proto-Scandinavian, so it dates and localizes the $\bar{a}$ stage in the North; its application to West Germanic rests on the daughter correspondences above.

The change affected stressed syllables only. Ringe and Taylor restrict it explicitly: unstressed $*\bar{e}$ did not lower but was eventually shortened, as in $*fadēr > *fader$ ‘father’ (Ringe and Taylor 2014, 13, and p. 147); in the runic material the unstressed final vowel of *fapīR* ‘father’ has already merged with $*i$ (Stiles 2017, 4). Within stressed syllables, however, the lowering was unconditioned: it applied before nasals exactly as elsewhere, and Ringe and Taylor accordingly print the intermediates $*mānō$ ‘moon’, $*mānōp$ ‘month’, and $*spānuz$ ‘spoon’ (Ringe and Taylor 2014, 11). The later, dialectally narrower fates of this $*\bar{a}$ — fronting in the North Sea area when oral, rounding when nasalized — are separate sound changes treated in their own chapters.

The reconstruction of the intermediate value is disputed. The objection is an old one: Bennett observed that the received account obliges Gothic to move $\bar{e}$ to $\bar{æ}$ and back to $\bar{e}$, and the non-West-Saxon dialects and Old Frisian to run through $\bar{e} > \bar{æ} > \bar{a} > \bar{æ} > \bar{e}$, “with no apparent agreement among the languages and no discernible phonological trend”, and that the Proto-Germanic $\bar{æ}$ is on that account preserved directly nowhere (Bennett 1950, 232–33, 235). In its place he proposed that the backing to $\bar{a}$ began in the north of the Germanic homeland and spread southward, never reaching Gothic in the east or Anglian and Frisian in the west, so that West Saxon $\bar{æ}$ is a retention of the intermediate stage rather than a re-fronting (Bennett 1950, 234–35). Fulk argues in the same direction on modern evidence: the Northwest Germanic vowel was a low front $*\bar{æ}$, retained unchanged in Anglo-Frisian, with the backing to $\bar{a}$ of Norse and inner West Germanic a separate areal development spreading northward from Upper German territory; on that reading the runic ηa spellings write a front $[\bar{æ}]$ for which the futhark had no better grapheme (Fulk 2018, 60–61, §4.6). Campbell is deliberately noncommittal, finding the $*\bar{a}$ stage “tempting to assume, though not definitely demonstrable” (Campbell 1959, 50–51, §§128–129). Ringe and Taylor answer with the lengthened place-adverbs *pār* ‘there’ and *hwār* ‘where’, whose front vowels are most naturally the output of fronting applied to a back $*\bar{a}$ (Ringe and Taylor 2014, 13–14). The present model adopts the two-step reconstruction while recording that the alternative remains live. Campbell is deliberately noncommittal, finding the $*\bar{a}$ stage “tempting to assume, though not definitely demonstrable” (Campbell 1959, 50–51, §§128–129). Ringe and Taylor answer with the lengthened place-adverbs *pār* ‘there’ and *hwār* ‘where’, whose front vowels are most naturally the output of fronting applied to a back $*\bar{a}$ (Ringe and Taylor 2014, 13–14). The present model adopts the two-step reconstruction while recording that the alternative remains live.

8.2 SC024. Lowering of stressed long $\bar{e}$ (PNWGmcLongELowering)

```
define PNWGmcLongELowering [  
  {*\bar{e}} -> {*\bar{a}}  
];
```

The rule reads the stressed tier **ē* only, in keeping with the stress restriction; unstressed **ē*, as in **fadēr* ‘father’, is left for the unstressed-shortening rules of the Old English stage and never lowers. No segmental environment is imposed: nasal forms such as **ménōþz* ‘month’ and **spénuz* ‘spoon’ pass through **mānōþ-* and **spānuz* on their way to *mōnaþ* ‘month’ and *spōn* ‘spoon’, exactly as reconstructed by Ringe and Taylor (Ringe and Taylor 2014, 11).

The rule stands near the head of the cascade, before the genuinely West Germanic innovations such as early *i*-apocope, **ij*-contraction, and *j*-gemination — the placement follows from the dating: the second-century runic evidence puts the lowering among the earliest Northwest Germanic developments, well before the changes that separate West Germanic from Norse. Its output **ā* is consumed much later in the cascade by SC102 EAFHiatusWInsertion, SC025 EAFLongANasalRounding, and SC101 EAFLongAFronting: if the lowering is instead displaced after those rules, **ménōþz* ‘month’ yields *†mānaþ* rather than OE *mōnaþ* ‘month’, **sképq* ‘sheep’ yields *†scāp* rather than *scēap* ‘sheep’, and **séanq* ‘to sow’ never acquires the hiatus-filling *w* of *sāwan* ‘to sow’. Within the cascade no earlier boundary has been demonstrated; the second-century runic attestation supplies the absolute dating.

9 Early i-apocope

9.1 Historical discussion

Sievers/Brunner treats the early loss of final **i* after unstressed syllables as established by the fact that these endings no longer trigger later i-umlaut in Old English, and Ringe and Taylor make the same point through the pathway to *geogub* ‘youth’ (Brunner 1965, sects 145–146; Ringe and Taylor 2014, 141). Campbell’s *dugup* ‘troop’ and *geogup* ‘youth’ examples belong to the same pattern (Campbell 1959, sect. 332).

The ending vowel disappears in a weak suffixal environment early enough to block later umlaut. This anti-umlaut chronology distinguishes the change from later final-vowel losses.

9.2 SC006. Early i-apocope (PWGmcEarlyIApocope)

```
define PWGmcEarlyIApocope [  
  {*i} -> Ø || PGmcStarStressedVowel PGmcStarConsonant+ PGmcStarVocalic  
  ⇨ PGmcStarConsonant+ _ .#.,  
  {*i} -> Ø || PGmcStarStressedVowel PGmcStarConsonant+ PGmcStarVocalic  
  ⇨ PGmcStarConsonant+ _ {*z} .#.  
];
```

The absence of umlaut in *geogub* ‘youth’ provides the historical argument for early deletion. The ordered derivation supplies a different test: if apocope is delayed until after SC034 OEAwLong-Diphthong, PGmc **skáwōθi* ‘shows’ yields *†scēawep* rather than expected OE *scēawap* ‘shows’.

Early i-apocope must therefore precede the long-diphthong development. Moving it earlier within the tested range leaves every output unchanged; its early date rests on the anti-umlaut evidence, not on a lower boundary supplied by the witness words.

10 Final *ō-lowering before *r

10.1 Historical discussion

Ringe and Taylor separate two points here: a broader shortening of vowels before word-final *r in unstressed syllables (for which kinship *r-stems such as PGmc **fadér* > PWGmc **fader* are a key diagnostic), and the specific *ō-before-*r development needed here (Ringe and Taylor 2014, 58–59). The direct lexical witnesses for *ō in that environment are two independent etyma: PGmc **fedwōr* ‘four’ with WGmc reflexes OE *fēower* ‘four’, OFris *fiuwer* ‘four’, OS *fiuwar* ‘four’; and PGmc **watōr* ‘water’ with OE *wæter* ‘water’.

The rule is historically secure but narrow: final or pre-final *ō before word-final *r. The clearest evidence remains concentrated in the four and water material. No broader environment for *ō is attested.

10.2 SC007. Lowering of final bimoric *ō before *r (PWGmcFinalOrLowering)

```
define PWGmcFinalOrLowering [  
  { *ō } -> { *a } || _ { *r } .#.  
];
```

OE *wæter* ‘water’ reveals why lowering must precede SC043 EAFBrightening. If SC007 PWGmcFinalOrLowering is delayed until afterwards, PGmc **wátōr* ‘water’ yields [†]*water* rather than expected OE *wæter* ‘water’: brightening can affect the vowel only after lowering has created its input. Moving the change earlier within the tested range alters no output.

The witness thus supplies a terminus ante quem at brightening but no earlier boundary. Comparative support for the *ō-before-*r rule comes from the two lexical witnesses **fedwōr* ‘four’ and **watōr* ‘water’ and their WGmc reflexes; kinship *r-stems belong to the broader pre-*r shortening context, not to a direct *ō > *a control. Within CAPR, *wæter* ‘water’ is the form that establishes ordering before brightening. No broader lowering of *ō is attested.

11 Coronal-w assimilation

11.1 Historical discussion

Ringe and Taylor treat the assimilation of **dw* and **zw* to **ww* as a shared Proto-West-Germanic innovation supported by one example of each input cluster (Ringe and Taylor 2014, 56–57; Stiles 1985, 89–94). The **dw* example is the numeral ‘four’: PGmc **feðwor* (Gothic *fidwor*) → WGmc **fewwar* → OE *fēower*, Old Frisian *fiuwer*, Old Saxon *fiuwar*. The **zw* example is the second-person plural pronoun, where two oblique case forms show the change: acc./dat. PGmc **izwiz* (Gothic *izwis*) → OE *eow*, Old Frisian *iu*, Old Saxon *iu*, OHG *iu*; and gen. Ringe and Taylor’s PGmc **izweraz* (Gothic *izwara*) → OE *eower*, OHG *iuwer* (Ringe and Taylor 2014, 56). Stiles discusses the same pronominal material using his own reconstruction conventions and explicitly treats Gothic *izwara* among the relevant comparanda (Stiles 1985, 89–94). These two case forms belong to a single pronominal paradigm, not to two independent etyma.

The historical support rests on a small witness set. Both coronal inputs assimilate before **w*, but the evidence for each cluster is confined: the numeral alone supplies the **dw* instance, and the oblique case forms of the second-person plural pronoun supply the **zw* instance. Both clusters are now witnessed in the corpus: ‘four’ for **dw*, and ‘you’ — selected in its dat.(-acc.) plural cell **izwiz* — for **zw*, deriving through **iwwi*, apocopated **iww*, to OE *ēow* ‘you’ (Ringe and Taylor 2014, 41–42, §3.1.1; Fulk 2018, sect. 8.3, pp. 204–205).

11.2 SC008. Assimilation of coronal consonants before **w* (PWGmcCoronalWAssimilation)

```
define PWGmcCoronalWAssimilation [  
  {*d} -> {*w} || - {*w},  
  {*z} -> {*w} || - {*w}  
];
```

OE *fēower* ‘four’ exposes a feeding relation: coronal assimilation must create **ww* while simplification can still reduce it. If SC008 PWGmcCoronalWAssimilation is delayed until after SC031 OEWWsimplification, PGmc **fedwōr* ‘four’ yields *†fēowwer* rather than expected OE *fēower* ‘four’. Earlier placements alter no output.

The numeral fixes that relative order. The pronoun now fixes a second one: assimilation must precede rhotacism (SC003 EAFRhotacism). The **z* of **izwiz* stands between vowel and **w*; had rhotacism applied first, it would have produced *†irwiz*, from which OE *ēow* ‘you’ can never be derived. The executable cascade composes the assimilation well before rhotacism, and the corpus derivation of *ēow* ‘you’ fails if the two are reversed. ‘Four’ remains the sole **dw* witness and the sole source of the coronal-assimilation → *ww*-simplification ordering constraint. The earlier boundary of the assimilation remains undetermined.

12 *ij*-contraction in *friend*

12.1 Historical discussion

Ringe and Taylor describe a change of **ijo* to **iu* in the ancestor of *friend*, with the pathway PGmc **frijōnd-* (Gothic *frijonds*) → PWGmc **friund* → OE *frēond*, Old Frisian *frīund*, Old Saxon *friund*, Old High German *friunt* (Ringe and Taylor 2014, 62). The same source immediately warns that the **ijo* sequence is unique enough that wider generalization is inadvisable (Ringe and Taylor 2014, 62). Luick (printed p. 118) notes that *iu* generalised within several *j*-stem paradigms through a related but differently conditioned loss of *j*, but does not supply a second example of the exact stressed **ijo* sequence (Luick 1914–1940, 118).

The change concerns a rare sequence attested only in the **frijōnd-* etymon and cannot safely be generalized into a broadly productive rule.

12.2 SC009. *ij*-contraction in *friend* (PWGmcIjContraction)

```
define PWGmcIjContraction [  
  {*i} {*j} {*ō} -> {*iu} || _ EnglishStarConsonant,  
  {*ī} {*j} {*ō} -> {*íu} || _ EnglishStarConsonant  
];
```

Only the **frijōnd-* etymon tests this contraction. If the rare **ijō* sequence survives until after SC032 OEDiphthongLeveling, PGmc **frijōndz* ‘friend’ yields *†friund* rather than expected OE *frēond* ‘friend’; moving contraction earlier within the tested range changes no output.

That single contrast places SC009 PWGmcIjContraction before diphthong leveling but gives no lower boundary. It cannot establish a productive sound law beyond the **frijōnd-* etymon, precisely the reservation made by Ringe and Taylor.

13 West Germanic j-gemination

13.1 Historical discussion

Fulk treats West Germanic consonant gemination before *j after a short vowel as a regular development and illustrates it with forms such as OE *settan* ‘set’ and *lecgan* ‘lay’ (Fulk 2018, 127, §6.15).

The change applies specifically after a short vowel before *j, not to geminate consonants generally.

13.2 SC010. West Germanic j-gemination (PWGmcJGemination)

```
define PWGmcJGemination [  
  {*p} -> {*p} {*p} || EnglishStarShortVowel _ {*j},  
  {*b} -> {*b} {*b} || EnglishStarShortVowel _ {*j},  
  {*t} -> {*t} {*t} || EnglishStarShortVowel _ {*j},  
  {*d} -> {*d} {*d} || EnglishStarShortVowel _ {*j},  
  {*k} -> {*k} {*k} || EnglishStarShortVowel _ {*j},  
  {*g} -> {*g} {*g} || EnglishStarShortVowel _ {*j},  
  {*f} -> {*f} {*f} || EnglishStarShortVowel _ {*j},  
  {*s} -> {*s} {*s} || EnglishStarShortVowel _ {*j},  
  {*m} -> {*m} {*m} || EnglishStarShortVowel _ {*j},  
  {*n} -> {*n} {*n} || EnglishStarShortVowel _ {*j},  
  {*l} -> {*l} {*l} || EnglishStarShortVowel _ {*j},  
  {*ŋ} -> {*ŋ} {*ŋ} || EnglishStarShortVowel _ {*j},  
  {*x} -> {*x} {*x} || EnglishStarShortVowel _ {*j}  
];
```

OE *nett* ‘net’ fixes the order because the syllabic-*j* development would remove the glide that conditions gemination. If SC011 PWGmcSyllabicJ precedes SC010 PWGmcJGemination, PGmc **nátjɑ* ‘net’ yields [†]*nete* rather than expected OE *nett* ‘net’. Earlier movement of gemination changes no output.

The chronology is phonologically transparent: the consonant must geminate before *j ceases to be consonantal. The witness establishes no earlier boundary.

14 Syllabic j after final-vowel loss

14.1 Historical discussion

Ringe and Taylor state directly that after final unstressed **a* and **ą* were lost, postconsonantal **j* became syllabic **i*, with outcomes behind OE *here* ‘army’ and *rice* ‘kingdom’ (Ringe and Taylor 2014, 46).

The sources establish the development, although the lexical evidence supplies little independent support for its position. Its scope is postconsonantal *j*, not high-vowel vocalization generally.

14.2 SC011. Syllabic **j* after final-vowel loss (PWGmcSyllabicJ)

```
define PWGmcSyllabicJ [  
  {*j} {*a} -> {*i} || EnglishStarShortVowel EnglishStarConsonant _ .#.,  
  {*j} {*ą} -> {*i} || EnglishStarShortVowel EnglishStarConsonant _ .#.  
];
```

The same PGmc **nátją* ‘net’ witness supplies the only firm boundary. Placing SC011 PWGmcSyllabicJ before SC010 PWGmcJGeminatio yields [†]*nete* rather than expected OE *nett* ‘net’; moving it later changes no output.

Comparative evidence establishes postconsonantal **j* to syllabic **i* after final unstressed **a* or **ą* loss, with *here* ‘army’ and *rice* ‘kingdom’ as outcomes. The lexicon adds only that vocalization followed gemination, not where it falls among subsequent changes.

15 Simplification of the cluster *xs before a consonant

15.1 Historical discussion

The change treated here is narrow. When *x stood before *s and that *s was itself followed by a further consonant, the *x was lost and the cluster was reduced. Campbell states the rule in exactly these terms, that when a consonant follows, *xs becomes s, and he illustrates it with *wæstm* ‘growth’ and *wæsma* ‘growth’ beside *weaxan* ‘to grow’, and with Northumbrian *sesta* ‘sixth’ beside West Saxon *siexta* (Campbell 1959, 170, §417). Brunner gives the same statement and adds that the following consonant may be *j* as well as a true obstruent, citing *nēosian* ‘to visit’, *þisl* ‘pole’, *wæsma* and *wæstm* (Brunner 1965, 184, §221.2). Bülbring formulates it as a pre-English change and is careful to say that it held as a rule, with exceptions (Bülbring 1902, 215, §527).

The cluster that the change requires is a specific one, and two neighbouring clusters show that the restriction is real. Where *xs stood with no consonant after it, the *x was not lost at all. It survived long enough to cause breaking and then hardened to the sound written *x*, that is [ks], as in *fox* ‘fox’, *siex* ‘six’, *weaxan*, *oxa* ‘ox’ and *fleax* ‘flax’ (Campbell 1959, 170, §416). Where *x stood before a single consonant it was likewise kept. Campbell observes that once *xs had become [ks], the only group in which *x still stood before a voiceless consonant in earliest Old English was *xt, and that this group remained, as in *feohtan* ‘to fight’, *miht* ‘might’, *niht* ‘night’ and *sōhte* ‘sought’ (Campbell 1959, 186, §464). The contrast is attested outside English as well. Old High German and Old Saxon *lastar* ‘reproach’ comes from **laxstra-* with the *x lost before *st, while Old English *leahtor* comes from **laxtra-* with the *x kept before *t (Campbell 1959, 170, §417).

The change is not Proto-Germanic. Gothic keeps the *h of this cluster in *bi-niuhšjan* ‘to spy out’ and *saihta* ‘sixth’, so the loss must be later than the separation of Gothic (Ringe and Taylor 2014, 157–58). Campbell reports the loss from the whole West Germanic area and from North Germanic as well, citing Old Norse *ísl* ‘axle’ and *nýsa* ‘to investigate’, Old Saxon *weslon* ‘to exchange’, *wastum* ‘growth’ and *niustan*, and Old High German *niusen* ‘to try’ (Campbell 1959, 170, §417). Ringe and Taylor set out the same comparative material and reach a more guarded conclusion. They derive Proto-Germanic **niuhšjaną* through Proto-West Germanic **niusjan* to Old English *nēosan* ‘to seek out, to visit’, and **sehstō* to Northumbrian *sesta*, and they take the Old Saxon agreement in *wastum*, *thisla* and *niusian* to show a shared northern West Germanic change. Against that they weigh the competition between *þixl* ‘pole’ and *þisl* ‘pole’ in early Mercian, the survival of *x in *eaxl* ‘shoulder’ from **ahslu*, and the retention in Old High German *sehsto* and *dihšala*. Their conclusion is that the *h was lost, possibly variably and possibly only in some dialects, when two or more consonants followed, and that the loss may have been in part a parallel development in the diverging Northwest Germanic dialects (Ringe and Taylor 2014, 157–58). The existence of the change is therefore secure while its exact date and extent are not, and the rating given here reflects that division.

Two chronological anchors are available. Ringe and Taylor place the loss after the Proto-West Germanic syncope of *-CijV-, since it is that syncope which brings the *s and the *j of **niuhšjan* together (Ringe and Taylor 2014, 157). They place it before breaking, observing that the undiphthongized vowels of *wæstm* ‘growth’ and *þisl* ‘pole’ can be accounted for only by supposing that these *h were lost before breaking took place (Ringe and Taylor 2014, 158). The rule is stated between those two points.

One witness in this collection undergoes the change. Proto-Germanic **funxstiz* ‘fist’ reaches the rule as **fūxstiz*, the long vowel having been produced by the Proto-Germanic loss of a nasal before *x described in SC103 PGmcNasalLossBeforeX. The cluster *xst is then reduced to *st, and the word continues to Old English *fȳst* ‘fist’. The comparative set for this particular word is West Germanic throughout, with Old Frisian *fēst* ‘fist’, Old Saxon and Old High German *fūst* ‘fist’, Dutch *vuist* and German *Faust* (Kroonen 2013, 160; Orel 2003, 157). Neither Gothic nor Old Norse preserves a reflex of it, so the word bears on the domain of the change rather than on its date.

The word *thought* is the control. Proto-Germanic **θánxtē* also passes through SC103 PGmcNasalLossBeforeX, which leaves **θāxtē*, but the *x there stands before a single *t and not before *s, so the present rule does not touch it and Old English has *þōhte* ‘thought’ with its *h* intact. The pair

fist and *thought* reproduces within this collection the same contrast that *lastar* and *leahtor* show across the West Germanic languages.

The relation between the two rules should not be overstated. The earlier rule does supply the cluster that this one simplifies, but the order of the two is established by their stages and not by any word in this collection. If the present rule were stated first, *fist* would still reach *fȳst* ‘fist’, because removing the *x from **funxstiz* leaves a nasal before s, and that nasal is removed with compensatory lengthening by the North Sea Germanic nasal-spirant law. The outcome is overdetermined, and the chronology rests on Gothic *bi-niuhsjan* ‘to spy out’ and *saihsta* instead.

15.2 SC028. Simplification of *xs before a consonant (PNWGmcPreconsonantalXLoss)

```
define PNWGmcPreconsonantalXLoss [  
  {*x} -> 0 || _ {*s} EnglishStarConsonant  
];
```

The *s in the structural description carries the whole weight of the rule. Without it the rule would delete *x before any two consonants, and it would then wrongly remove the first element of a geminate *xx before *j, where Old English in fact has *hliehhan* ‘to laugh’ with the geminate written *hh* (Campbell 1959, 186, §464). The rule fires on *fist* and on no other word in this collection, and it leaves *fox*, *six*, *wax*, *flax* and *ox* untouched, as it must, along with *thought*, *fight*, *night*, *light*, *might*, *knight*, *fright* and *wight*.

The implementation name retains an older description of the rule and will be brought into line in a separate pass.

16 *lp*-voicing

16.1 Historical discussion

Ringe and Taylor treat word-internal **lp* > **ld* as a regular sound change in northern West Germanic and illustrate it with forms such as *fealdan* ‘fold’, *beald* ‘bold’, *wuldor* ‘glory’, and *gylden* ‘golden’ (Ringe and Taylor 2014, 170–71). Campbell gives a similar West-Germanic-facing formulation with examples such as *fealdan*, *wuldor*, *beald*, *gold* ‘gold’, and *feld* ‘field’ (Campbell 1959, 169, §414).

The comparative evidence supports *lp* > *ld* most clearly in northern West Germanic, not as an unqualified pan-PWGmc development.

16.2 SC012. Northern West Germanic *lp*-voicing (EAFLThVoicing)

```
define EAFLThVoicing [  
  {*θ} -> {*d} || {*l} _  
];
```

The *field*, *fold*, *gold*, and *wold* families preserve **lp* to **ld*, but none dates the change against a neighboring rule. Every output remains unchanged when the voicing is moved in either direction.

Comparative reconstruction therefore establishes northern West Germanic *lp* > *ld*, but the witness forms fix no date. Neither a pan-PWGmc attribution nor an exact local placement follows from the evidence presented here.

17 Dental hardening

17.1 Historical discussion

Ringe and Taylor state directly that in PWGmc voiced dental fricative **ð* became stop **d* in all positions (Ringe and Taylor 2014, 43).

The change is systemic across early West Germanic and extends beyond any one lexical family.

17.2 SC013. Dental hardening (PWGmcDentalHardening)

```
define PWGmcDentalHardening [  
    {*ð} -> {*d}  
];
```

Dental hardening has systemic scope: voiced fricative **ð* became stop **d* throughout early West Germanic. Moving SC013 PWGmcDentalHardening earlier or later changes no output.

Comparative evidence establishes the sound law; the present lexicon leaves its exact position approximate.

18 Northwest Germanic u-lowering

18.1 Historical discussion

Northwest Germanic lowered **u* to **o* when the following syllable contained a non-high vowel. Campbell describes the change and lists *ġeoc* ‘yoke’ among its regular outcomes (Campbell 1959, 42–43, §115); Fulk gives the same word as a standard example — “OIcel. ok, OE *geoc*, OHG *joh* beside *juh* and OS *juk*” — and notes the paradigmatic alternation between lowered and unlowered stems that the conditioning produced (Fulk 2018, 56, §4.3). A word-initial **j* does not block the change: the blocking effect of *j* concerns only a consonantal *j* standing between the target vowel and the conditioning vowel, as in the class I weak verbs of the *cnyssan* ‘strike’ type (Fulk 2018, 56, §4.3). Ringe and Taylor accordingly reconstruct the Proto-West Germanic paradigm of ‘yoke’ with the lowering applied (Ringe and Taylor 2014, 129).

The clearest corpus witnesses are *ġeoc* ‘yoke’, *nosu* ‘nose’, *šcofl* ‘shovel’, and *sorg* ‘sorrow’. Where the following syllable kept a high vowel the lowering did not apply, as in *ġeogub* ‘youth’, whose root *u* survived (Brunner 1965, 64–65, §92.1).

18.2 SC017. Lowering of **u* before following non-high vowels (PNWGmcULowering)

```
define PNWGmcULowering [  
  {*u} -> {*o}  
  || .#. EnglishStarConsonant* _  
    [EnglishStarConsonantNoJ - EnglishStarNasal]  
    EnglishStarConsonantNoJ* EnglishStarNonHighVowel,  
  {*ú} -> {*ó}  
  || .#. EnglishStarConsonant* _  
    [EnglishStarConsonantNoJ - EnglishStarNasal]  
    EnglishStarConsonantNoJ* EnglishStarNonHighVowel  
];
```

Lowering of *u* to *o* is fixed on both sides by *ġeoc* ‘yoke’, *nosu*, *šcofl* ‘shovel’, and *sorg*.

The lowering feeds the much later West Saxon palatal-glide spelling (SC016 OEWsPalatalGlide): the *o* that the scribes wrote in *ġeoc* ‘yoke’ is the output of this change, so PGmc **júkq* ‘yoke’ passes through **jokq* on its way to the attested spelling (Fulk 2018, 56, §4.3; Ringe and Taylor 2014, 129). After SC019 PNWGmcFinalLongORaising, PGmc **núšō* ‘nose’ yields *†nusu* rather than expected *nosu*, PGmc **skúflō* ‘shovel’ yields *†šcufl* rather than expected *šcofl* ‘shovel’, and PGmc **šúrgō* ‘sorrow’ yields *†surg* rather than expected *sorg*. These witnesses place SC017 PNWGmcULowering before final long-*o* raising, and the *ġeoc* spelling shows its output surviving into the written record.

19 Stressed monosyllable **ō*-raising

19.1 Historical discussion

Campbell treats the development of final accented *ō* to *ū* in stressed monosyllables directly, with the familiar outcomes behind *cū* ‘cow’, *hū* ‘how’, *tū* ‘two’, and *bū* ‘both’ (Campbell 1959, 47, §122).

The change is historically secure, but the tested forms determine no close relative position for it. Its input is final **ō* in a stressed monosyllable.

19.2 SC018. Raising of final stressed monosyllabic **ō* (PNWGmcStressedMonosyllableORaising)

```
define PNWGmcStressedMonosyllableORaising [  
  {*ō} -> {*ū} || .#. [EnglishStarConsonant | EnglishPalatalConsonant]* _ .#.   
];
```

Campbell’s *cū* ‘cow’, *hū* ‘how’, and *tū* ‘two’ establish final stressed monosyllabic **ō* > **ū*.

Reversing SC018 PNWGmcStressedMonosyllableORaising with neighboring changes leaves every output unchanged. The sound change is secure, but its exact position in the early history of long vowels rests on the handbooks.

20 Raising of final unstressed long **ō*

20.1 Historical discussion

Ringe and Taylor describe the change of unstressed final non-nasalized long **ō* to short **u* as a Northwest Germanic development (Ringe and Taylor 2014, 30). It applies in the same final-syllable environment as the subsequent loss of word-final **z*. The derivation of *ræste* ‘rest’ fixes their local order: SC019 PNWGmcFinalLongORaising must still see final **ō*, and word-final **z*-deletion removes the following **z* only afterward.

The change supplies the final vowel of forms such as *nosu* ‘nose’, *šcofl* ‘shovel’, and *sorg* ‘sorrow’.

20.2 SC019. Raising of final unstressed long **ō* (PNWGmcFinalLongORaising)

```
define PNWGmcFinalLongORaising [  
  {*ō} -> {*u}  
  || EnglishStarVocalic  
  [EnglishStarConsonant | EnglishPalatalConsonant]+ _ .#.  
];
```

Two groups of witnesses confine final unstressed long **ō* > **u*. The forms *nosu* ‘nose’, *šcofl* ‘shovel’, and *sorg* ‘sorrow’ fix its lower boundary.

Before SC017 PNWGmcULowering, PGmc **núšō* ‘nose’ yields *†nusu* rather than expected OE *nosu* ‘nose’, PGmc **skúflō* ‘shovel’ yields *†šcufl* rather than expected *šcofl* ‘shovel’, and PGmc **súrgō* ‘sorrow’ yields *†surg* rather than expected *sorg* ‘sorrow’. After word-final **z*-deletion (SC020 EAffFinalZDeletion), PGmc **rástōz* ‘rest’ yields *†rast* rather than expected *ræste* ‘rest’. These failures place SC019 PNWGmcFinalLongORaising after u-lowering and before final z-loss.

21 Chapter 3. From Proto-West Germanic to Anglo-Frisian

21.1 Historical interval

This chapter covers the sound changes that occurred after the Proto-West Germanic period and before, or during the emergence of, the specifically English line. The starting reconstruction is Proto-West Germanic; the end point is the Anglo-Frisian ancestor required by the model's historical tree. Its existence and the identification of its innovations are separate questions. Its inventory must be reconstructed from conditioned laws and daughter chronologies, not from the traditional subgroup label alone.

21.2 A necessary terminological caution

The title of this chapter uses “Anglo-Frisian” as an organizing historical concept. That choice requires an explicit qualification.

The scholarly literature uses several overlapping terms for this developmental period:

- North Sea Germanic and Ingvaemonic: labels used by some scholars for a proposed subgroup comprising Old English, Old Frisian, and Old Saxon (or more narrowly, Old English and Old Frisian only). The innovations associated with this label — especially the nasal spirant changes and certain vowel developments — are sometimes described as diffusion rather than shared inheritance (Bremmer 2009, 24–27, 126–28).
- Anglo-Frisian: a label used specifically for the Old English / Old Frisian branch, or for innovations shared between the two languages. Its use presupposes a tighter relationship between English and Frisian than between either and Old Saxon.
- Proto-Anglo-Frisian (PAF): the strongest interpretation, positing a discrete reconstructed common ancestor for Old English and Old Frisian specifically. This is the position of Ringe and Taylor, who reconstruct a PAF stage between Proto-West Germanic and Proto-Old-English (Ringe and Taylor 2014, 54–68).

CAPR requires a discrete Anglo-Frisian ancestral node. This does not guarantee that every traditionally associated innovation is inherited from it, or exclusive to English and Frisian. A broader innovation can already be present in its input; similar daughter outcomes can also result from independent events. Authors' diffusion interpretations remain accurately attributed, but they cannot resolve an incompatible chronology within CAPR's ordered tree (Versloot 2017, 302–19; Bremmer 2008, 284, 292–93).

21.3 A worked historical tree test

If a supposed shared innovation obligatorily follows a daughter-only change in Frisian which English never underwent, it cannot occupy the common stem under those premises. Either the ordering or scope premise must change, the innovation happened independently, or the apparently identical events are historically different. The required ancestor is not removed.

Campbell reconstructs Frisian *au* contraction before ordinary fronting; Goblirsch instead proposes a shared diphthong followed by Frisian stress shift and contraction (Campbell 1939, 91, 104; Goblirsch 1991, 17, 20–21). The daughter-only event is a predecessor in the first account and a follower in the second. The second is compatible with sharing, but does not attest the reconstructed Frisian intermediate. Surface agreement, compatibility with inheritance, compelled parallelism under premises, and unresolved history must therefore remain distinct judgments.

21.4 The working account and why it is used

The English reconstruction adopted as a working scaffold is the conventional account developed by Campbell and critically refined by Ringe and Taylor. It distinguishes inherited long vowels from the long vowels produced by diphthong contraction, and it treats fronting, breaking, restoration and mutation as conditioned phonological developments. That scaffold is useful because it

specifies contrasting inputs and intermediate states, not because one author’s authority decides the history (Campbell 1959, 52–53, 60–72; Ringe and Taylor 2014, 170–73, 215–37).

The comparative specialists test particular load-bearing premises. Campbell’s argument about English and Frisian fronting, Versloot’s runic interpretations and Goblirsch’s proposed lost Frisian diphthong do not form one automatically compatible package (Campbell 1939, 90–91, 104; Versloot 2017, 295–97, 318; Goblirsch 1991, 17–21). Where an alternative changes the inherited inventory or the identity of an event, it must be evaluated as that alternative, not inserted into the conventional chain without its premises.

CAPR implements regular sound laws. Prosodic and phonological conditions may distinguish environments, but lexical diffusion, grammatical categories and individually selected exceptions cannot repair a contradiction. Paradigm remodeling and borrowing may affect which historical form a lexical entry represents; they are not thereby conditions on a sound law. This methodological choice is distinct from faithfully reporting an author’s different theoretical account.

21.5 Long vowels, diphthongs and the ancestral inventory

The inherited-long contrast is central. On the conventional reconstruction, inherited oral long **ā* has already acquired a front quality when English stressed **ai* completes its development to a new back **ā*. Otherwise the new vowel should share the inherited vowel’s fronting. Ringe and Taylor formulate this as a relation between temporal milestones: inherited-long fronting must be well under way before contraction completes. They allow overlap; a serial implementation is not proof that the changes occupied disjoint periods (Campbell 1939, 90; Ringe and Taylor 2014, 170).

The inherited vowel itself is disputed. Fulk’s retained-front reconstruction does not require precisely the same earlier backing and re-fronting as Ringe and Taylor’s account. That is a disagreement about the input inventory, not a small adjustment to the position of an otherwise identical rule (Fulk 2018, 60–61; Ringe and Taylor 2014, 10–13). Nielsen also proposes a different causal relation between contraction and long-vowel restructuring, allowing co-occurrence rather than imposing the conventional strict sequence (Nielsen 2001, 514–16, 521).

Luick’s proposed fronted-ai path is a further alternative, not an observed intermediate series. His conjecture is **æe > *æə > *æa > *ā*; the middle offglide is schwa. Campbell rejects that explanation, but the rejection is not an independent observation that such a phonetic path is impossible (Luick 1914–1940, 132–33; Campbell 1939, 90, n. 3). The inherited-long and secondary-long histories must consequently remain separate even where later mutation makes their final vowels converge.

Nasal environments require another distinction. Nasalization, loss of a nasal with compensatory lengthening, rounding and eventual merger are not one event. The nasalized input can escape an oral-fronting law before its later rounded outcome is established. A shared final vowel therefore does not place every substep at the same ancestral node (Bremmer 2009, 24–27; Ringe and Taylor 2014, 142–46).

The following table specifies the relevant inventory questions at a conservative ancestral cut. It is a working reconstruction, not a newly adjudicated full phoneme inventory. Earlier West Germanic developments can be inherited at this cut without being exclusively Anglo-Frisian innovations.

Input class	Conservative working ancestral state	English daughter consequence	Remaining premise
Inherited oral long vowel	Front long vowel under the conventional account	Subsequent dialectal and palatal treatment	Earlier back versus retained-front input
Nasal long vowel	Distinguished from the oral long vowel	Rounding and merger must be dated separately	Which nasal substeps precede the cut

Input class	Conservative working ancestral state	English daughter consequence	Remaining premise
Stressed ai	Retained diphthong before completed English contraction	Secondary back long vowel, eligible for later mutation	Runic interpretation and any limited ancestral onset
Ordinary short non-nasal a	Unfronted at this conservative cut	Ordinary English fronting	Daughter contraction before fronting
Inherited au	Not identified with completed English or Frisian outcome	English front element and later offglide development	Identity with ordinary short fronting
Supported inherited Vww classes	Earlier West Germanic reanalysis may already be present	Later English quantity and diphthong realization	Full quantity/glide domain and prosody
Velars and palatal tendencies	No blanket completed assibilation is stipulated	Class-specific daughter histories	Articulation, cutoff and merger are distinct

The evidence underlying these qualifications is component-specific (Ringe and Taylor 2014, 41–42, 65–66, 170–73; Versloot 2017, 295–97, 318; Laker 2007, 167–84). The table does not assign inherited-short fronting to the stem merely because the node is called Anglo-Frisian.

21.6 Alternative cuts and their tree consequences

A more expansive common-stem reconstruction is possible only with different premises. In Luick’s account, participation of the diphthong nucleus in fronting can coexist with a conjectured later Frisian development. In Goblirsch’s account, a common fronted au diphthong precedes Frisian stress shift and contraction. Both require historical intermediates whose existence must be argued, not obtained from the name of the subgroup (Luick 1914–1940, 130–33; Goblirsch 1991, 17, 20–21).

Proposed common-stem content	Required premise	Conditional consequence
Inherited-long restructuring, but retained ai and short a	Completed English contraction is later	Compatible conservative cut
Ordinary short fronting	Its secure predecessors can also occur before the split	Excluded if daughter-only English contraction obligatorily precedes it
Shared fronted-au development	Frisian stress shift/contraction follows that development	Compatible in Goblirsch’s account, not proof of inheritance
Shared consonantal palatalization	Corresponding consonant classes and necessary predecessors are genuinely identical	Unresolved; apparent similarities do not settle all layers

Campbell’s English chain makes the second row especially consequential: if completed contraction is English-only and ordinary fronting must follow it, the latter cannot be inherited from the common stem. The corresponding English and Frisian frontings are then parallel under those premises. Changing a disputed premise can change that conclusion, but cannot remove the required ancestor (Campbell 1939, 90–91; Versloot 2017, 295–97, 318).

21.7 Palatalization is not a single subgroup character

A palatal articulation can precede phonemic contrast, and the productive cutoff of a conditioning process can precede its eventual assimilated reflex. Fricative-g merger with j is different again. Geminate and postnasal stops, singleton fricatives, k, h and sk must not be treated as one dated change simply because later spellings look palatal (Hogg 1979, 100–111; Laker 2007, 167–68, 175–84).

The shared-palatalization hypothesis must therefore identify which layer is inherited. A daughter-specific predecessor can exclude a completed component from the stem without excluding every earlier articulatory tendency. Conversely, removing an argument against sharing establishes compatibility, not that one common event actually occurred (Laker 2007, 175–84). The vowel diphthongization following initial palatals is another event; Luick explicitly distinguishes the similar Frisian and English outcomes (Luick 1914–1940, 162–63).

21.8 What the runes date

An inscription dates a written object. A sound-change terminus additionally requires the reading, etymology, linguistic affiliation and relation of the grapheme to phonetic or phonemic structure. The interpretation of the Caistor inscription as retaining ai and the interpretation of Frisian retention are consequential but conditional (Versloot 2017, 295–97, 318). Waxenberger likewise distinguishes early allophonic mutation from later phonemicization and lacks immediate runic evidence for every short-vowel split (Waxenberger 2019, 63–74).

No one calendar date is therefore attached here to every change described as Anglo-Frisian. The English discussion that follows starts from the working inventory and makes its necessary daughter developments explicit. Canonical classification, preferred reconstruction and an unresolved component are kept distinct until individual adjudication.

21.9 Major changes and their historical basis

21.9.1 West Germanic rhotacism (SC003)

The medial change of *z to *r in environments such as **déuzaz* ‘deer’, **xúrdaz* ‘hoard’, and **líznojaną* ‘learn’ is historically a post-Proto-West-Germanic development. Ringe and Taylor argue that rhotacism was not inherited from Proto-Northwest Germanic and was not uniform within West Germanic (Ringe and Taylor 2014, 52, 98, 102). Crist separates this change explicitly from the deletion of word-final *z and argues that rhotacism must follow the deletion rules (Crist 2001, 104–6; 2002, 1, 4). Bammesberger gives the standard Old English-facing summary: *z yielded *r in intervocalic position but was generally lost in final position (Bammesberger 1992, 39).

The CAPR rule is named EAFRhotacism, placing it in the Early Anglo-Frisian corridor, CAPR’s operational post-Proto-West-Germanic stage on the English line; the reader-facing chapter label describes the change as a West Germanic rhotacism.

21.9.2 Word-final *z deletion (SC020) and the three final-*z developments

The loss of word-final *z is not one process but three historically distinct developments, and this chapter contains two of them. The central one, SC020, is the Proto-West Germanic loss of *z in unstressed syllables, seen in forms such as **rástōz* ‘rest (nom.sg.)’ and stated for the whole branch by Ringe and Taylor (Ringe and Taylor 2014, 44–45); Crist’s analysis distinguishes it both from the earlier NWGmc changes and from the later narrower Ingvaemonic deletion rules (Crist 2002, 1, 4). Earlier still, the consonant-stem root nouns had generalized endingless nominatives before Proto-West Germanic (SC096, Chapter 2). Later, and only in the north, *z was lost in stressed monosyllables with compensatory lengthening (SC097, this chapter); the southern dialects instead retained and rhotacized it. The standard handbooks confirm the West Germanic deletion in general terms: Bammesberger gives a clean statement that Germanic *z is generally lost in final position (Bammesberger 1992, 39); the three-way division refines those summaries rather than contradicting them.

The CAPR rule for the unstressed loss is still named `EAFfinalZDeletion`, an identifier that predates the restaging of the change to Proto-West Germanic; the name is retained as a stable identifier pending a global renaming pass, and the historical stage recorded in the staging metadata takes priority over the name prefix. SC020 remains presented in this chapter, beside rhotacism, because the two changes jointly determine the fate of every remaining **z*.

21.9.3 Anglo-Frisian ai-monophthongization (SC004)

The English outcome of stressed/root **ai* is **ā*. Versloot distinguishes an early velar-conditioned Frisian contraction from later non-velar treatment, with mutation and delabialization intervening (Versloot 2017, 302–9, 316). His wave account is an author’s interpretation, not CAPR’s own genealogy. Each component must instead be tested for common-stem versus daughter placement.

The current SC004 `EAFaiMonophthongization` models English contraction after SC101 `EAFLongAFronting`. The new ai-derived **ā* escaped the earlier fronting of inherited oral **ā*; Campbell states that inference and Ringe and Taylor retain it (Campbell 1959, 52–53, §132; Ringe and Taylor 2014, 169–70). Soul provides another implementation boundary at interstress raising, not the sole historical argument or proof of inherited contraction.

The unstressed development **ai* > **ē* (in final and nonfinal syllables) is a separate and earlier Proto-Northwest Germanic change (SC014), discussed in Chapter 2; its corpus witnesses are the dative-singular endings of *span* (**spánnai* ‘span’ > *spanne* ‘span’) and *meed* (**mízdai* ‘meed’ > *meorde* ‘meed’).

21.9.4 Anglo-Frisian brightening (SC043, treated in Chapter 4)

The fronting of low **a* to **æ* outside nasal environments is traditionally called Anglo-Frisian brightening. The name does not establish one inherited event. It executes later in the cascade than the changes of this chapter, so its full section appears in Chapter 4; it is introduced here because it anchors the “Anglo-Frisian” label that names this period. Campbell gives the classical statement: “By a very early change Prim. Gmc. *a* > *æ* in OE and OFris. when not followed by a nasal consonant” (Campbell 1959, 52, §131). The traditional name also appears in modern comparative treatments; it does not independently establish a shared event (Fulk 2018, 72–73).

The change is notable for what follows it: OE Breaking presupposes the fronted input; OE a-Restoration partially undoes it in back-vowel environments. The three-change sequence is the conventional English working account, but its components and conditioning remain individually arguable. Versloot proposes restricted early fronting and late e-breaking; final forms can coincide under front-and-restore and never-front histories (Versloot 2025, 123, 125–28, 131–35).

Campbell notes that English and Frisian may not simply reflect one undifferentiated shared pre-historic event, and Ringe and Taylor leave open whether the wider spread of fronted outcomes happened mainly on the continent or in Britain (Ringe and Taylor 2014, 60–62). CAPR’s implementation treats the change as a single rule; the book prose acknowledges the uncertainty about its exact geographical scope.

The current canonical historical classification is early Anglo-Frisian with Anglo-Frisian scope, while the section is presented in Chapter 4. It remains the incumbent pending adjudication, not an answer to the comparative controversy. English plain-a/au process identity is distinct from inherited stem identity. Their executable rules remain provisional separate representations.

21.10 Cascade vs. historical order in this chapter

The sections follow executable serialization so that derivations are inspectable. That order is not an independently demonstrated total historical chronology. The broader final-z loss, later northern loss and rhotacism are distinguished by their actual environments (Ringe and Taylor 2014, 44–45; Crist 2002, 1, 4).

Earlier-stage proxies remain in this editorial corridor. The cluster change represented by SC022 `PNWGMcMnDissimilation` and final-n loss represented by SC023 `PNWGMcNStemNLoss` are clas-

sified as Common Germanic/Proto-Germanic despite retained name prefixes (Fulk 2018, 121; Ringe 2017, 101–3). The retired unstressed-o raising is not an active member. Book order, computational position and historical stage must remain separate.

22 West Germanic final *z-deletion

22.1 Historical discussion

Word-final *z in unstressed syllables was lost in Proto-West Germanic. Ringe and Taylor state the change for the whole branch and illustrate it with the nominative plural **dagōz* > **dagō* and the consonant-stem nominative **fadurz* > **fadur*, noting that the ending is lost after consonants as well as after vowels (Ringe and Taylor 2014, 44–45, §3.1.1). Crist’s handout formulates the same development and its Ingvaemonic sequels (Crist 2002, 2, §§5–6). The change is pan-West-Germanic, not specifically Ingvaemonic: every West Germanic daughter shows the loss, and the Friesland comb inscription *kaba* < **kambaz* ‘comb’ (c. 250–300 CE) supplies early epigraphic confirmation (Fulk 2018, 25, n. 1).

The conditioning segment is specifically the voiced sibilant *z, never *s: Ringe and Taylor’s near-minimal pair of nominative singular **dagaz* > **dag* beside genitive singular **dagas*, which keeps its sibilant into Old English *dægēs*, shows that the change reads the Verner voicing distinction (Ringe and Taylor 2014, 212, §6.1). Where the handbooks disagree about whether a given ending had *-s or *-z — as for the nominative plural **ōz* — the disagreement matters directly to whether this rule applies (Ringe and Taylor 2014, 115–16, §4.2.1).

This is the middle of three historically distinct final-*z developments, and Ringe and Taylor explicitly separate it from the later loss in stressed monosyllables, citing Crist’s demonstration that they are two changes (Ringe and Taylor 2014, 44–45, §3.1.1). Earlier, the consonant-stem (root-noun) nominatives of monosyllables had already generalized endinglessness before Proto-West Germanic (SC096 RootNounNomZLoss), so forms like **bōkz* ‘book’ never reach this rule with their marker intact. Later, and only in the north, *z was lost in stressed monosyllables with compensatory lengthening (SC097 MonosyllabicFinalZLoss); the present rule leaves stressed monosyllables untouched. Older accounts that grouped all of these under one loss of final *z, such as Campbell’s, are superseded by this three-way division (Campbell 1959, 166).

At the boundary with Chapter 2’s Northwest Germanic sequence, the derivation of *ræste* ‘rest’ shows that final *ō-raising (SC019 PNWGMcFinalLongORaising) must precede this rule: raising applies to *ō but not to *ōz, whose final vowel is still sheltered by the sibilant when raising runs (Ringe and Taylor 2014, 15–16, 24). On the later side, Ringe and Taylor order the loss of *z before the loss of word-final bare *-a, since **dagaz* first becomes **daga* and only then **dag* (Ringe and Taylor 2014, 45–46, §3.1.2).

22.2 SC020. West Germanic final *z-deletion (EAFinalZDeletion)

```
define EAFinalZDeletion [{*z} -> 0 ||
  .#. ?* EnglishStarVocalic
    [EnglishStarConsonant | EnglishPalatalConsonant]+
    EnglishStarVocalic ?* _ .#. ,
  .#. [EnglishStarConsonant | EnglishPalatalConsonant]*
    EnglishStarVocalic+
    [EnglishStarConsonant | EnglishPalatalConsonant]+ _ .#.] ;
```

The rule deletes word-final *z in unstressed syllables, stated through two environments. The first clause covers polysyllables, where the final syllable of these corpus forms is unstressed: this is the ordinary case, with 110 corpus derivations, such as PGmc **bārdaz* ‘beard’ on its way to OE *beard* ‘beard’ and **rāstōz* ‘rest’ on its way to *ræste* ‘rest’. The second clause covers post-consonantal *z in monosyllables. By the time this rule runs, SC096 RootNounNomZLoss has already removed the genuine root-noun nominative endings, so the only form reaching the second clause is **frījōndz* ‘friend’, contracted to monosyllabic **frīundz* by SC009 PWGMcIjContraction; its ending, like that of **fadurz*, stood in an unstressed syllable when the Proto-West

Germanic change applied and so belongs here rather than to the root-noun development (Ringe and Taylor 2014, 44–45, §3.1.1). Stressed monosyllables ending in vowel plus *z meet neither clause and are left for SC097 MonosyllabicFinalZLoss.

The chronology of word-final *z-loss is unusually well delimited: *ræste* ‘rest’ supplies its early boundary, while later weak syllables supply its late boundary.

Before SC019 PNWGmcFinalLongORaising, PGmc **rástōz* ‘rest’ yields †*rast* rather than expected OE *ræste* ‘rest’. After SC040 OEMedUnstressedULowering, PGmc **bébruz* ‘beaver’ yields †*befro* rather than expected *befer* ‘beaver’, PGmc **kwéðuz* ‘cud’ yields †*cwedo* rather than expected *cwedu* ‘cud’, and PGmc **fēlθuz* ‘field’ yields †*feldo* rather than expected *feld* ‘field’, alongside eight other newly failing rows. Final z-loss therefore follows SC019 PNWGmcFinalLongORaising and precedes SC040 OEMedUnstressedULowering.

The **rástōz* ‘rest’ derivation fixes the local relation to SC019 PNWGmcFinalLongORaising. The distant boundary at SC040 OEMedUnstressedULowering shows only that word-final *z-loss precedes the later weak-syllable sequence; its placement within that wider interval follows the handbook chronology after final **ō*-raising.

23 Early apocope in unstressed words

23.1 Historical discussion

Alongside the regular loss of word-final short high vowels in third syllables (SC006 PWGmcEarlyIApocope), Ringe and Taylor identify a second, earlier apocope: “Short high vowels were also lost after heavy syllables in unstressed words” (Ringe and Taylor 2014, 57–58, §3.1.4). The two laws must not be conflated. Fully stressed disyllables kept their final **i* long enough to cause i-umlaut — OE *giest* ‘guest’ < **gastiz* and *fȳr* ‘fire’ < **fūri* require exactly that survival (Ringe and Taylor 2014, 55, §3.1.4) — whereas words that carried no sentence stress lost the vowel already in Proto-West Germanic.

The conditioning is prosodic. Like Verner’s law, the change is governed by accent: it applied in words unstressed in the sentence, and its apparent exceptions are systematic, not sporadic. Forms such as OE *ymbe* ‘around’ and OHG *umbi* kept their final vowel because, as Ringe and Taylor observe, proclitics “were not phonologically word-final” and so stood outside the environment altogether (Ringe and Taylor 2014, 57–58, §3.1.4). Sentence-level accent placement therefore decides which sandhi variant each daughter language continues, and doublets across the family reflect the stressed and unstressed sentence forms of the same word — regular sandhi, not lexical diffusion.

The diagnostic witness is the second-person plural pronoun. Ringe and Taylor print the Proto-West Germanic form as a doublet: PGmc **izwiz* (Gothic *izwis*) → **iwwi* (by SC008 PWGmcCoronalWAssimilation and the loss of final **z*, SC020 EAFFinalZDeletion) → PWGmc **iuwi* ~ **iuw* (Ringe and Taylor 2014, 41–42, §3.1.1). Old English continues the apocopated, unstressed variant, and Ringe and Taylor’s proof is the vocalism itself: “OE *iow* ‘you (dat. pl.)’ definitely does [show early apocope] (since it does not exhibit i-umlaut)” (Ringe and Taylor 2014, 57–58, §3.1.4). Had the **i* survived, i-umlaut (SC055 OEIUmlaut) would have fronted the diphthong; West Saxon *ēow* ‘you’ beside early West Saxon and Northumbrian *iow* ‘you’ shows the normal unumlauted development (Campbell 1959, sect. 702, p. 283).

23.2 SC098. Early apocope in unstressed words (PWGmcUnstressedWordFinalIApocope)

```
define PWGmcUnstressedWordFinalIApocope [  
  {*i} -> Ø || {*w} {*w} _ .#.   
];
```

The corpus transcription does not mark the absence of word stress, so the rule states the law through a proxy environment: word-final **i* after the geminate **ww* created by coronal-w assimilation, which in the present corpus is exactly coextensive with the law’s unstressed-word domain. The same convention serves SC096 RootNounNomZLoss, where a development whose true conditioning the notation cannot yet express is likewise implemented over an exactly coextensive segmental environment.

The corpus witness is ‘you’: **izwiz* → **iwwiz* (assimilation) → **iwwi* (final **z*-loss) → **iww* (this rule) → OE *ēow* ‘you’. The chronology is fixed on both sides. The rule is fed by the loss of final **z* (SC020 EAFFinalZDeletion), since only that loss makes the **i* word-final; and it must precede i-umlaut (SC055 OEIUmlaut) — that ordering is Ringe and Taylor’s own dating argument, for an unapocopated **iwwi* ‘you’ surviving to the umlaut period would yield an unumlauted diphthong and a form other than the attested *ēow* ‘you’. The rule applies within Proto-West Germanic, before the later northern loss of final **z* in stressed monosyllables (SC097 MonosyllabicFinalZLoss): Ringe and Taylor treat the apocope among the Proto-West Germanic final-syllable developments and print the apocopated variant as a Proto-West Germanic form (Ringe and Taylor 2014, 41–42, 57–58). Fully stressed disyllables are untouched, as the history requires: **gastiz* and **fūri* pass through unchanged and duly umlaut to *giest* ‘guest’ and *fȳr* ‘fire’.

The surviving word-final geminate **ww* is then vocalized to a long diphthong (SC033 OEEwLongDiphthong) before geminate simplification (SC031 OEWWsimplification) can destroy it — Ringe

and Taylor date that vocalization to Proto-West Germanic itself (**fewwar* → PWGmc **feubar*) (Ringe and Taylor 2014, 41–42, §3.1.1; Fulk 2018, sect. 8.3, pp. 204–205) — giving **ēoww*, simplified to **ēow*, the attested Old English form.

24 Northern monosyllabic final *z-loss

24.1 Historical discussion

Long after the Proto-West Germanic loss of final *z in unstressed syllables (SC020 EAffFinalZDeletion), the northern West Germanic dialects lost word-final *z in stressed monosyllables as well, with compensatory lengthening of a short nucleus. Ringe and Taylor’s witness set is OE *mā* ‘more’ < **maiz*, the pronouns *wē* ‘we’, *gē* ‘you’, *mē* ‘me’, *bē* ‘thee’, *hē* ‘he’, *hwā* ‘who’ < **hwaz*, and — hedged in their own print with question marks — *cū* ‘cow’ (Ringe and Taylor 2014, 86, §3.3.1). The southern dialects retained the sibilant and rhotacized it: Old High German *mīr*, *wīr*, *mēr*, *ēr* answer the Old English endingless forms, which is why Fulk counts this loss among the diagnostic Ingvaenonic features (Fulk 2018, 18, n. 6). Ringe and Taylor explicitly treat this as a change separate from the Proto-West Germanic unstressed loss, citing Crist’s demonstration that the two must be distinguished (Ringe and Taylor 2014, 44–45, §3.1.1).

The scholarship disagrees about the exact conditioning, and the disagreement is worth recording. An older account, represented by Campbell and going back to Luick, derived the endingless pronouns from unaccented sentence variants rather than from a regular sound change (Campbell 1959, 166; Luick 1914–1940, 819). Ringe and Taylor reject that analysis because *mā* ‘more’ and *cū* ‘cow’ are not plausibly unaccented words (Ringe and Taylor 2014, 86, §3.3.1). Crist formulates an Ingvaenonic rule in which *z is lost after front vowels, with compensatory lengthening, covering preconsonantal cases as well; his data contain no word-final back-vowel monosyllables, so forms like **hwaz* and the ancestor of *cū* fall outside what his statement can decide — a documented gap rather than a refutation (Crist 2002, 1, 4, §§1, 10). Kilday narrows the preconsonantal subcase to Old Saxon and Old Frisian while accepting the word-final monosyllabic loss for Old English, contrasting regular *meord* ‘reward’ with the loanword-influenced *mēd* ‘reward’ (Kilday 2024, 1–3). CAPR adopts Ringe and Taylor’s quality-neutral formulation because it alone generates the back-vowel witnesses, while noting that the front-vowel forms are compatible with both analyses.

Apparent counterexamples are analogical, not phonological: OE *dēor* ‘deer’, *ār* ‘oar’, and *gār* ‘spear’ show final -r from levelling out of inflected forms where the sibilant was word-internal and regularly rhotacized, not from retention of word-final *z (Ringe and Taylor 2014, 86, §3.3.1, n. 24). The change precedes rhotacism (SC003 EAFRhotacism), which Ringe and Taylor place last in this sequence of northern developments (Ringe and Taylor 2014, 87, §3.3.1).

The corpus now witnesses this change directly. The interrogative pronoun ‘who’ is selected in its nominative singular masculine cell, PGmc **hwaz* (Gothic *hwas*), precisely the form Ringe and Taylor cite for this loss (Ringe and Taylor 2014, 86, §3.3.1): the rule lengthens the short nucleus and deletes the sibilant, giving **hwā*, whence OE *hwā* ‘who’. The resulting back vowel never undergoes Anglo-Frisian brightening — “**hwāe* does not exist”, as Campbell puts it (Campbell 1959, sect. 125, p. 49; Brunner 1965, sect. 137 Anm. 1, p. 129) — so the derivation ends with the attested form. Other members of Ringe and Taylor’s witness set remain outside the corpus because it selects oblique or plural cells for them — ‘cow’ and ‘meed’, for instance, enter the cascade in inflected forms whose *z, where present, is word-internal.

24.2 SC097. Northern monosyllabic final *z-loss (MonosyllabicFinalZLoss)

```
define MonosyllabicFinalZLoss [  
  {*a} -> {*ā}, {*á} -> {*ā},  
  {*e} -> {*ē}, {*é} -> {*ē},  
  {*i} -> {*ī}, {*í} -> {*ī},  
  {*o} -> {*ō}, {*ó} -> {*ō},  
  {*u} -> {*ū}, {*ú} -> {*ū}  
  || .#. [EnglishStarConsonant | EnglishPalatalConsonant]*  
  _ {*z} .#. ]  
] .o. [  
  {*z} -> 0 ||  
  .#. [EnglishStarConsonant | EnglishPalatalConsonant]*
```

The rule first lengthens a short nucleus standing immediately before word-final *z in a monosyllable, then deletes the *z after any vowel in a monosyllable. The principal synthetic controls run the change on Ringe and Taylor’s own witnesses, fed to the rule in their chronologically correct intermediate shapes. Short-nucleus inputs show both halves of the change at once: *hwaz yields *hwā and *hiz yields *hī, each with loss of the sibilant and compensatory lengthening (Ringe and Taylor 2014, 86, §3.3.1). A form whose nucleus is already bimoric skips the lengthening step and simply loses the sibilant: *maiz yields *mai at this stage, with its diphthong intact; the attested OE *mā* ‘more’ arises only later, when the stressed monophthongization (SC004 EAFaiMonophthongization) takes *ai to *ā. The word ‘cow’, whose history Ringe and Taylor themselves print with question marks and whose analysis remains disputed, is deliberately not used as a principal control; a long-vowel input of that shape (*kūz yielding *kū) merely repeats what *maiz already demonstrates, and the word’s evidentiary weight is discussed in the historical dossier rather than leaned on here.

The corpus derivation of *hwā* ‘who’ now fixes this rule’s position empirically as well as philologically. It stands after SC020 EAffFinalZDeletion, since the two losses are historically distinct changes with the unstressed loss earlier (Ringe and Taylor 2014, 44–45, §3.1.1). Rhotacism (SC003 EAFRhotacism) follows in the executable cascade as in the historical account: Ringe and Taylor place rhotacism after this loss, at the end of the sequence of *z-losses (Ringe and Taylor 2014, 87, §3.3.1), and the cascade composes it immediately after this rule, so a sibilant removed here can never surface as -r — were the order reversed, *hwaz would rhotacize to *hwar and ‘who’ could never be derived; the negative controls below confirm this. Consonant-final monosyllables are untouched: their nominative *-z, where it ever existed, was eliminated before Proto-West Germanic under SC096 RootNounNomZLoss. Word-internal *z, as in PGmc *déuzq ‘deer’ on its way to OE *dēor* ‘deer’, does not meet the environment of this rule and duly rhotacizes.

25 West Germanic rhotacism

25.1 Historical discussion

Bammesberger states that Germanic **z* yielded **r* in intervocalic position in Old English, while final **z* was generally lost (Bammesberger 1992, 39). Ringe and Taylor argue that this merger of **z* with **r* was independent in Norse and West Germanic and belongs after the Proto-West-Germanic stage (Ringe and Taylor 2014, 52, 98, 102). Crist likewise places rhotacism after earlier West Germanic **z*-deletion rules and rejects treating it as an inherited Proto-Northwest-Germanic innovation (Crist 2001, 104–6; 2002, 1, 4).

The internal identifier SC003 EAFRhotacism places the change in CAPR’s Early Anglo-Frisian corridor, the operational post-Proto-West-Germanic stage on the English line; historically the change is a West Germanic rhotacism, later than Proto-Germanic. It is also distinct from SC020 EAffFinalZDeletion, which removes final **z* before the surviving medial consonant becomes **r*.

25.2 SC003. West Germanic rhotacism (EAFRhotacism)

```
define EAFRhotacism [  
  {*z} -> {*r} || EnglishStarVocalic _ ?  
];
```

Breaking supplies the decisive upper boundary. If rhotacism is delayed until after SC044 OEBreaking, PGmc **líznojaną* ‘learn’ yields *†lirnian* rather than expected OE *liornian* ‘learn’, PGmc **líznoþi* ‘learns’ yields *†lirnaþ* rather than expected *liornaþ* ‘learns’, PGmc **lízno* ‘learn’ yields *†lirna* rather than expected *liorna* ‘learn’, and PGmc **mízdai* ‘meed’ yields *†merde* rather than expected OE *meorde* ‘meed’. Moving rhotacism earlier within the tested range changes no output.

The lexical evidence thus supplies a terminus ante quem but no terminus post quem. The lower boundary rests on the historical analyses cited above: Ringe and Taylor put rhotacism at the end of the sequence of **z*-losses — “first **z* was lost in a variety of environments ..., then all surviving **z* became **r*” (Ringe and Taylor 2014, 87, §3.3.1) — and Crist observes that the deletions distinguish **z* from **r* and so must precede the merger (Crist 2002, 2–3). The rule is accordingly ordered after the three final-**z* losses (SC096 RootNounNomZLoss, SC020 EAffFinalZDeletion, and SC097 MonosyllabicFinalZLoss) and before breaking, so that the derivation follows the reconstructed chronology.

26 *mn*-dissimilation

26.1 Historical discussion

In the inherited *n*-stem paradigm the zero-grade oblique cells brought *m* and *n* into direct contact, and in that adjacent cluster the labial nasal dissimilated to a labial spirant: *mn* > *βn* (surfacing as *fn*). Old Norse preserves the older paradigmatic distribution, with the labial confined to the oblique cluster (*himinn* ‘heaven’ beside dative *hifni*); Old English and Old Saxon generalized it. Fulk treats the cluster change among developments common to Germanic, while warning that its surface results are irregular and that reverse *bn* > *mn* is later well attested in Northwest Germanic (Fulk 2018, 121, §6.11). The relevant *heofon* ‘heaven’ and *mōnaþ* ‘month’ material is discussed by Campbell (Campbell 1959, 189, 195, §§470, 484).

The underlying cluster change is therefore late Proto-Germanic / Common Germanic, not securely a pan-Northwest-Germanic innovation; PNWGmc remains a stable executable identifier only. The lexical evidence does not constrain a positive local cascade position.

26.2 SC022. Dissimilation of adjacent *mn* (PNWGmcMnDissimilation)

```
define PNWGmcMnDissimilation [  
  {*m} -> {*β}  
  || EnglishStarVocalic _ {*n}  
];
```

The rule fires only where *m* stands directly before *n*. It supplies the labial of *stefn* ‘stem, trunk’ from the *mn*-cluster of the *stamn*-family, and it is the historical change behind the labial of *heofon* ‘heaven’, which was generalized from the oblique cluster into the vowel-bearing stem before the Old English vocalic changes. (An earlier cross-syllable formulation that labialized an intervocalic *m* before a later nasal has been retired: it simulated paradigm levelling rather than a sound law.)

Moving SC022 PNWGmcMnDissimilation earlier or later leaves every output unchanged. Its executable place in this holding zone is therefore editorial/computational, while its historical classification rests on the handbook account of *mn*-dissimilation.

27 Word-final *n*-loss

27.1 Historical discussion

The change isolated here is far older than its position in the cascade suggests: it is the general (pre-)Proto-Germanic loss of word-final **n*, with nasalization of the preceding vowel, in polysyllables. Ringe’s proof set for the law spans the whole grammar — nouns such as **yugón* > **juką* ‘yoke’, pronouns such as **tón* > **panō*, and even the verb form **dedō* ‘I did’ — so it is general phonology, not a fact about any one declension (Ringe 2017, 101–3). Gothic *tuggo* shares the weak nominative-singular outcome, and the nasalized reflex **ō* remained contrastive into Proto-West Germanic before yielding OE *-e* (Ringe and Taylor 2014, 54–55, 58–59).

Within the present corpus the change surfaces in exactly one shape: the weak nouns are cited in the stem form **-ōn-*, and this rule carries them to the Proto-Germanic nominative singular in **-ō*, as in **túngōn* > **túngō* > *tunge* ‘tongue’, alongside *eorpe* ‘earth’, *heorte* ‘heart’, *nædre* ‘adder’, and thirteen further weak nouns. The masculine weak nominative singular in trimoric **-ō* never had a final **-n* to lose, and Proto-Germanic **sebun* ‘seven’, **nigun* ‘nine’, and **tehun* ‘ten’ kept their *-n* by lexical analogy among the numerals (Ringe 2017, 103); the rule’s narrow **-ōn* environment leaves all of these correctly untouched.

27.2 SC023. Loss of word-final **n* after **ō* (PNWGmcNStemNLoss)

```
define PNWGmcNStemNLoss [  
  {*ō} {*n} -> {*ō̃} || _ .#.  
];
```

The verb *dōn* ‘do’ supplies the negative, counterfeeding witness for the chronology. PGmc **dōnq* ‘do’ passes this rule untouched; only SC047 OEHeavySyllableNasalApocope later strips the final **q* and creates a new word-final **-ōn*. That secondary **-n* survives into *dōn* precisely because the old loss was no longer active: if SC023 PNWGmcNStemNLoss is displaced after the apocope, it consumes the new nasal and the derivation collapses entirely (+?).

The retained *-n* of *dōn* ‘do’ therefore supplies a terminus ante quem for the loss — it must be dead before the apocope — while the seventeen weak nouns above are its positive witnesses; the lower boundary remains unattested within the cascade, as befits a change already complete in Proto-Germanic.

28 Nasal spirant changes

28.1 Historical discussion

Germanic lost nasal consonants before voiceless fricatives twice, in two changes that are easily confused because their outcomes look alike. Both replace a sequence of vowel, nasal and fricative with a long nasalized vowel and the fricative. They differ in date, in geography, and in which fricatives they affect.

The earlier change is common Germanic and is treated in the opening chapter of this book, on the Proto-Germanic loss of a nasal before **x*. Its results are shared by every daughter language, and only **a*, **i* and **u* occur in its input (Campbell 1959, 44, §119; Fulk 2018, 55, §4.1; Ringe 2017, 149–50, §3.2.7).

The later change belongs to the dialects bordering the North Sea, that is to Old English, Old Frisian and Old Saxon, the group traditionally called Ingvaemonic. Here the groups **mf*, **ns* and **nþ* likewise reject the nasal with compensatory lengthening and nasalization (Campbell 1959, 47, §121; Fulk 2018, 72, §4.11; Brunner 1965, 176, §186.1; Luick 1914–1940, 276, §301.1). Ringe and Taylor call it the most obvious phonological innovation of the northern dialects and list some thirty examples, among them **gans* ‘goose’ and **jugunþi* ‘youth’ (Ringe and Taylor 2014, 139–41). Campbell describes it as a later change similar to the common Germanic one, and Fulk as comparable to it; neither treats them as the same law.

The two are told apart by what the languages outside the North Sea area show. The common Germanic change left no nasal anywhere, so Old High German has *fūht* ‘damp’ and *fūst* ‘fist’ exactly as Old English does. The later change was confined to the north, so the cognates of its witnesses keep the nasal: Old High German *fimf*, *gans*, *ander*, *jugund* answer Old English *fif* ‘five’, *gōs* ‘goose’, *ōþer* ‘other’, *ġeoguh* ‘youth’. On this test **funhsti-* ‘fist’, whose long vowel is shared by Old High German *fūst*, Dutch *vuist* and German *Faust*, belongs to the earlier change and not to the North Sea law at all (Kroonen 2013, 160).

Where the vowel was **a*, the long nasalized vowel that this law produced was afterwards rounded to *ō* in Anglo-Frisian, which is why Old English has *gōs* ‘goose’, *tōþ* ‘tooth’ and *ōþer* ‘other’. That rounding is a third change again, and it is the same rounding that gives *fōn* ‘seize’ and *þōhte* ‘thought’ from the common Germanic law and *mōna* ‘moon’ and *spōn* ‘chip’ from inherited long *ā* before a surviving nasal; Campbell states that it reached all three sources at one and the same time (Campbell 1959, 50, §128 n. 1; Brunner 1965, 33, §26; Fulk 2018, 72, §4.11). It is treated in the chapter on the rounding of the long nasalized low vowel. That the vowel was rounded and did not simply merge shows that its nasality survived the law that created it: as Fulk observes, it did not fall together with the *ā* that came from **ai* (Fulk 2018, 55, §4.1). Ringe and Taylor take the nasalization to have remained subphonemic until it was lost separately in each daughter (Ringe and Taylor 2014, 141). Old Saxon shares the loss of the nasal and the nasalization, and rounds only variably, which is why the law itself is described as North Sea Germanic and the rounding as Anglo-Frisian (Campbell 1959, 47, §121; Fulk 2018, 72, §4.11).

The North Sea Germanic law is a single connected sound change: in every handbook account the nasal is lost *with* compensatory lengthening, and the lengthening is the compensation for the loss. It is stated here as two rules only because the vowel must be adjusted while the conditioning nasal is still present, before the nasal can be removed. The order of SC026 EAFNasalSpirantLengthening before SC027 EAFNasalSpirantLoss is a requirement of the statement, not evidence for two successive historical stages.

28.2 SC026. North Sea Germanic nasal-spirant law, first step (EAFNasalSpirantLengthening)

```
define EAFNasalSpirantLengthening [  
  {*a} -> {*ā} || _ EnglishStarNasal EnglishStarNSGmcSpirant,  
  {*i} -> {*ī} || _ EnglishStarNasal EnglishStarNSGmcSpirant,  
  {*u} -> {*ū} || _ EnglishStarNasal EnglishStarNSGmcSpirant,  
  {*á} -> {*ā} || _ EnglishStarNasal EnglishStarNSGmcSpirant,
```

```

    { *i } -> { *ī } || _ EnglishStarNasal EnglishStarNSGmcSpirant,
    { *ú } -> { *ū } || _ EnglishStarNasal EnglishStarNSGmcSpirant
];

```

The environment is nasal plus **f*, **þ* or **s*. The fricative **x* is excluded: nasal loss before **x* is the earlier change stated as SC103 PGmcNasalLossBeforeX. Campbell names the groups **mf*, **ns* and **nþ*, Fulk says the change affects **mf*, **ns* and **nþ*, Sievers and Brunner name the fricatives **f*, **þ* and **s*, and no example in Ringe and Taylor’s list contains **x* (Campbell 1959, 47, §121; Fulk 2018, 72, §4.11; Brunner 1965, 176, §186.1; Ringe and Taylor 2014, 139–41). As in the earlier change, only **a*, **i* and **u* occur. The outcome of **a* is the long nasalized **ā*, which SC104 EAFNasalized-LowRounding later rounds; the outcomes of **i* and **u* are written **ī* and **ū*, their nasality having no further consequence (Campbell 1959, 47, §121).

Two witnesses apply in the present corpus. PGmc **gánsz* ‘goose’ becomes **gāns* ‘goose’, and PGmc **júgunθ* ‘youth’ becomes **júgūnθ* ‘youth’. In *geogub* ‘youth’ the syllable carrying the lengthened vowel is unstressed, and the length is given up again by the later shortening of unstressed syllables; Sievers and Brunner note the same course in *berap* ‘they carry’ from **beranþi* ‘they carry’ through **berōþ* ‘they carry’ (Brunner 1965, 176, §186.1 Anm. 3; Luick 1914–1940, 276, §301.1).

If the rule is stated after the loss of the nasal, PGmc **gánsz* ‘goose’ yields *†geas* in place of *gōs* ‘goose’, and PGmc **júgunθ* ‘youth’ yields *†geogob* in place of *geogub* ‘youth’. This shows only that the vowel must be adjusted before its conditioning nasal is removed. It does not establish a date for either operation, and no earlier or later boundary is claimed here.

28.3 SC027. North Sea Germanic nasal-spirant law, second step (EAFNasalSpirantLoss)

```

define EAFNasalSpirantLoss [
    EnglishStarNasal -> 0 || _ EnglishStarNSGmcSpirant
];

```

The nasal is removed in the environment that conditioned the lengthening, giving **gās* ‘goose’ and **júgūθ* ‘youth’. The rule completes the statement of the single change begun in SC026 EAFNasalSpirantLengthening; the two are not independent sound laws. The converse test, stating the loss first, merely reproduces the same two wrong forms. Nothing in the material fixes a later boundary for the loss.

29 The hiatus-breaking *w* of the *verba pura*

29.1 Historical discussion

The small class of Germanic strong verbs whose roots ended in a vowel, the *verba pura*, reached Northwest Germanic with a morphologically expected hiatus. Ringe and Taylor reconstruct Proto-Germanic **sēanq* ‘to sow’ (Gothic *saian*), which the Northwest Germanic lowering of **ē₁* carried to **sāanq*; the West Germanic languages then “exhibit innovative consonants that eliminated” the hiatus (Ringe and Taylor 2014, 12). The repair differs by branch, and the difference dates and localizes the change. Old English and Old Frisian inserted *w*, as in Old English *sāwan* ‘to sow’ and Old Frisian *sāwinge* ‘sowing’ beside *grōwinge* ‘growth’, while Old Saxon and Old High German used *j* (*sāian* ‘to sow’, *sāen* ‘to sow’, *sājen* ‘to sow’) (Ringe and Taylor 2014, 12, 151). The insertion of *w* is therefore an Anglo-Frisian development and the consonant of *sāwan* is not inherited; it must not be projected back into the protoform.

The origin of that *w* is neither inherited nor morphological. Þórhallsdóttir, in the standard treatment of the problem, rejects in turn the derivation of the West Germanic *w* from a Proto-Indo-European *u*-perfect (Þórhallsdóttir 1993, 115–17), from a **ue/o*-present (Þórhallsdóttir 1993, 117–19), and from the transfer of a preterite *w* into the present (Þórhallsdóttir 1993, 121–22). The *w* “rather has an inner-Germanic phonological explanation” (Þórhallsdóttir 1993, 136). It began as an ordinary phonetic glide filling the hiatus, and it began in one narrow environment, before **u*. The cells in question, as Bremer had already seen, are the first singular and first plural of the present indicative together with the plural of the reduplicated preterite in **-um*, **-uþ*, **-un* (Þórhallsdóttir 1993, 120). Þórhallsdóttir sets out the pre-Old English present indicative with the hiatus still intact, first singular **sā’u*, second **sā’is*, third **sā’iþ*, first plural **sā’um*, second plural **sā’iþ*, third plural **sā’anþ*, and observes that “the glide *w* was a natural hiatus filler before the *u* of the endings of the 1st person singular and plural” (Þórhallsdóttir 1993, 127). The preterite stem **seuwun* arose by the same insertion before the **u* of the plural endings (Þórhallsdóttir 1993, 126).

From those few cells the *w* was carried through the whole paradigm by analogy. Three forces converge. Levelling proceeded out of the **u*-cells themselves; the preterite stem **seuw*, **seuwun* “would have assisted in extending the new *w* to all forms of the present paradigm” and to the preterite participle; and verbs with an etymological **w*, above all *flōwan* ‘to flow’ from the root **pleu-*, exerted their own attraction (Þórhallsdóttir 1993, 127). The result, complete already in pre-Old English, is the uniform pattern **sāwan*, **seuw*, **seuwun*, **sāwan-* (Þórhallsdóttir 1993, 136). Old Frisian inherits the same generalized type, so that its *w* and the Old English *w* are one Anglo-Frisian event (Þórhallsdóttir 1993, 130, 134). The scattered *w*-forms of Old High German are a separate and later inner-German development and are not to be identified with it (Þórhallsdóttir 1993, 119, 123).

This layering matters for how the rule below should be read. Old English citation forms are infinitives, and the infinitive **sā’an* is precisely one of the cells that never received *w* by the phonological rule, so the *w* of *sāwan* ‘to sow’ is analogical. The rule therefore models the outcome of the generalization, and its environment, any vowel after *ā*, is a citation-form proxy for a paradigm-wide result. It is not a reconstruction of the conditioning of the original insertion.

The chronology is fixed on both sides by Ringe and Taylor. The *w* must postdate the West Germanic loss of intervocalic **w*, or the new glide would itself have been swept away (Ringe and Taylor 2014, 151, n. 9); and it “must have occurred early enough to prevent fronting of **ā*” in pre-Old English (Ringe and Taylor 2014, 151). The whole reason *sāwan* ‘to sow’, *cnāwan* ‘to know’, *blāwan* ‘to blow’, and *māwan* ‘to mow’ keep their back vowel is that the *w* was already in place when the North Sea Germanic fronting applied. Since it is the generalized *w* that stands in the infinitive, this later boundary constrains the generalization itself. The rule accordingly stands before the fronting in the cascade, even though on the present corpus the two orders happen to produce the same outputs, since the fronting rule as implemented does not touch a prevocalic *ā* in any case; the ordering encodes the historical chronology, and no corpus-internal contrast demonstrates it. That chronology rests on Ringe and Taylor alone, for Þórhallsdóttir’s chapter nowhere discusses the fronting of **ā* and supplies no independent evidence for the order.

29.2 SC102. Generalized hiatus-breaking *w* after long *ā* (EAFHiatusWInsertion)

```
define EAFHiatusWInsertion [  
  [...] -> {*w} || {*ā} _ EnglishStarVocalic  
];
```

The rule is fed by SC024 PNWGmcLongELowering, which creates the *ā*-initial hiatus it repairs; **séanq* ‘to sow’ passes through **sāanq* to **sāwanq* on its way to *sāwan* ‘to sow’. Displaced before the lowering, the rule can never apply, since the root vowel is still **ē* and no hiatus after *ā* exists, and the derivation loses its consonant altogether.

Its output in turn feeds the blocking environment of SC101 EAFLongAFronting: the inserted *w* is precisely what shields the *ā* of *sāwan* ‘to sow’ from fronting, as treated in that chapter. The corpus carries *sāwan* as the diagnostic witness of the class; *cnāwan* ‘to know’, *blāwan* ‘to blow’, *māwan* ‘to mow’, *wāwan* ‘to blow (of wind)’, and *prāwan* ‘to turn’ instantiate the same derivation (Ringe and Taylor 2014, 151).

30 North Sea Germanic nasalization of long $\bar{a}$ before a nasal

30.1 Historical discussion

In the dialects along the North Sea coast the long low vowel $*\bar{a}$ — centrally the vowel produced from $*\bar{e}_1$ by the Northwest Germanic lowering — was nasalized when a nasal consonant followed and survived. The nasalized vowel was afterwards rounded in Anglo-Frisian, which is why Old English has *mōna* ‘moon’, *mōnaþ* ‘month’ and *spōn* ‘spoon’ against Old High German *māno* ‘moon’, *mānōd* ‘month’, *spān* ‘spoon’ and Old Norse *máni* ‘moon’, *mánaðr* ‘month’, *spánn* ‘spoon’. Campbell describes the split of Germanic $\bar{e}^1$ before nasals in these terms and identifies the vowel that the rounding operated on as a nasalized and unrounded $*\bar{q}$ [Campbell (1959), p. 50, §127; p. 50, §128 n. 1]. Fulk places the rounded outcome of $*\bar{e}$ before nasals among the Anglo-Frisian changes and derives it from an earlier nasalized vowel (Fulk 2018, 72–73, §4.12).

The nasalization and the rounding have different geographies, and separating them resolves an apparent disagreement in the handbooks. Ringe and Taylor state that stressed low vowels were nasalized in the northern West Germanic dialects, Old Saxon among them (Ringe and Taylor 2014, 142, §5.1.2); Old Saxon accordingly shows *ōdar* ‘other’ and *sōd* ‘true’ beside unrounded *quān* ‘wife’ and *sāno* ‘immediately’ (Ringe and Taylor 2014, 150–51). What Old Saxon shares is the nasalization; what it shares only in part is the rounding, and for the vowel inherited from Proto-Germanic it does not share the rounding at all (Campbell 1959, 44, §119; Fulk 2018, 72, §4.11). The nasalization stated here is therefore North Sea Germanic, and the rounding treated in the chapter on the long nasalized low vowel is Anglo-Frisian.

The nasalization is the conditioned counterpart of the fronting of oral $*\bar{a}$ treated in the fronting chapter: a following nasal gives nasalization and eventual rounding, and its absence gives fronting. Together the two exhaust the fate of the old low vowel in this area. The comparative material does not order the two branches against each other, and no such ordering is claimed here.

30.2 SC025. Nasalization of long $\bar{a}$ before nasals (EAFLongANasalRounding)

```
define EAFLongANasalRounding [  
  {*\bar{a}} -> {*\bar{q}} || _ EnglishStarNasal  
];
```

The rule consumes the $*\bar{a}$ created by SC024 PNWGmcLongELowering: displacing the lowering after this rule leaves the nasalization without an input, and $*m\acute{e}n\bar{o}\theta z$ ‘month’ surfaces as $^{\dagger}m\bar{a}na\bar{p}$ in place of OE *mōnaþ* ‘month’, $*sp\acute{e}nuz$ ‘spoon’ as $^{\dagger}sp\bar{a}n$ in place of *spōn* ‘spoon’. Its output is consumed in turn by SC104 EAFNasalizedLowRounding, which supplies the rounded vowel that the two words actually show.

Equally important is what the rule must precede. The monophthongization of $*ai$ in SC004 EAFai-Monophthongization creates a new long $\bar{a}$, and that vowel was never nasalized and never rounded before nasals: *stān* ‘stone’ and *hām* ‘home’ keep $\bar{a}$. Stating the monophthongization before this rule makes the new vowel eligible for nasalization and hence for rounding, and the cascade then wrongly yields $^{\dagger}st\bar{o}n$ and $^{\dagger}h\bar{o}m$. This is the same chronological inference Campbell draws for the fronting: the treatments of the old low vowel were complete, or at least under way, before *ai*-monophthongization supplied a new one (Campbell 1959, 52–53, §132; Ringe and Taylor 2014, 169–70).

31 Anglo-Frisian rounding of the long nasalized low vowel

31.1 Historical discussion

Three separate developments described in earlier chapters end in the same sound: a long, nasalized, low vowel. The oldest is the Proto-Germanic loss of a nasal before **x*; the second is the North Sea Germanic nasal-spirant law; the third is the nasalization of the inherited long *ā* before a nasal that survived. In Old English and Old Frisian all three surface as *ō*, and Campbell states the unification without qualification: the nasalized vowel became identical with the *ō* inherited from Proto-Germanic already in prehistoric Old English, and the same change affected the nasalized vowel of the Proto-Germanic law and the nasalized vowel of the Ingvaeonic law at one and the same time (Campbell 1959, 50, §128 n. 1). One later sound change therefore accounts for all three, and the appearance of three independent roads to *ō* is an illusion created by looking only at the Old English surface.

That the intermediate vowel was nasalized and unrounded is shown by a form in which it was shortened very early. Campbell's example is *samcucu* 'half alive', where the shortened reflex is *a* and never *o*; the vowel that the earlier laws produced was therefore a nasalized **ā̃*, and the rounding is a distinct and later event (Campbell 1959, 50, §128 n. 1). Sievers and Brunner describe the same nasalized long vowel and its rounded Old English outcome [Brunner (1965), p. 33, §26; p. 58, §64].

The geography is Anglo-Frisian. Old Saxon nasalized its stressed low vowels along with the rest of the northern West Germanic area (Ringe and Taylor 2014, 142, §5.1.2), and it shares the loss of the nasal in both of the earlier laws; the categorical, systematic rounding, however, it does not share. For the Proto-Germanic nasalized low vowel Old Saxon retains *ā* consistently, and for the vowel created by the nasal-spirant law it has *ā* or *ō* according to word and dialect, while Old English and Old Frisian have *ō* throughout (Campbell 1959, 44, §119; Fulk 2018, 72, §4.11). That partial and lexically variable Old Saxon rounding is comparative evidence bearing on the innovation rather than participation in it. Ringe treats the rounding as a parallel development of the diverging northern dialects and locates it in the northernmost of them, that is in Anglo-Frisian (Ringe 2017, 149–50, §3.2.7; Ringe and Taylor 2014, 142, §5.1.2). Luick groups the whole set of changes among those peculiar to the Anglo-Frisian dialect group and notes that the nasalized vowel later gave up its nasality (Luick 1914–1940, 276, §301.1). The rounding is accordingly Anglo-Frisian, and the nasalization that feeds it is the wider North Sea Germanic property.

Ringe and Taylor confirm that a single rounding covers all the sources: the rounding affected the nasalized low vowels of the nasal-spirant law, the nasalized low vowels of the accompanying list, and the reflexes of Proto-Germanic **/anh/* alike (Ringe and Taylor 2014, 142, §5.1.2). The condition on the input is nasality and nothing else, which is why the long *ā* that Old English later won from **ai* escapes: that vowel was oral, and it came into being after the rounding had run its course. Fulk makes this the central argument for the long survival of the nasality, since the nasalized vowel developed to *ō* and did not fall together with Old English *ā* from **ai* (Fulk 2018, 55, §4.1).

31.2 SC104. Rounding of the long nasalized low vowel (EAFNasalizedLowRounding)

```
define EAFNasalizedLowRounding [  
  { *ā̃ } -> { *ō }  
];
```

The rule is unconditioned, since the vowel it operates on exists only where one of the three earlier changes created it. Its inputs arrive from SC103 PGmcNasalLossBeforeX, from SC026 EAFNasalSpirantLengthening and from SC025 EAFLongANasalRounding, and each of those three stands in a feeding relation to it: stated before any one of them, the rule leaves that source's nasalized vowel untouched and the cascade returns no form at all for its witnesses.

Four lexemes in the present corpus reach Old English through this rule, and between them they

witness all three sources. **gánsz* ‘goose’ arrives as **gā̃s* ‘goose’ from the North Sea Germanic law and gives *gōs* ‘goose’; **ménōθz* ‘month’ arrives as **mā̃nōþ* ‘month’ and gives *mōnaþ* ‘month’; **spénuz* ‘spoon’ arrives as **spā̃nu* ‘spoon’ and gives *spōn* ‘spoon’. The Proto-Germanic law contributes **θánxtē* ‘thought’, the preterite of the verb ‘to think’, which arrives as **θā̃xtē* ‘thought’ and gives *þōhte* ‘thought’. That is the very form cited for this rounding, beside Old Frisian *thochte*, and it is the evidence that the vowel did not fall together with the *ā* of *stān* ‘stone’ (Fulk 2018, 55, §4.1; Campbell 1959, 44, §119). The other firing of the Proto-Germanic law, the high vowel of *fȳst* ‘fist’, does not reach this rule at all.

The counterpart is what the rule leaves alone. **stáinaz* ‘stone’ and **xáimaz* ‘home’ acquire their long *ā* from SC004 EAFAiMonophthongization, which follows this rule, and their vowel was never nasalized; they surface as *stān* ‘stone’ and *hām* ‘home’. Placing the monophthongization before the nasalization and the rounding makes that vowel eligible and the cascade then yields *†stōn* and *†hōm*, which is the chronological inference Campbell draws for the treatments of the old low vowel generally (Campbell 1959, 52–53, §132; Ringe and Taylor 2014, 169–70).

32 North Sea Germanic fronting of long $\bar{a}$

32.1 Historical discussion

Long after the Northwest Germanic lowering of $*\bar{e}_1$ to $*\bar{a}$, the dialects of the North Sea coast fronted the surviving oral $*\bar{a}$ to a low front vowel: West Saxon $\bar{a}$ in *dēd* ‘deed’, *slāpan* ‘to sleep’, *lātan* ‘to let’, *rēdan* ‘to read’, and *māel* ‘meal’, against Anglian, Kentish, and Old Frisian $\bar{e}$ (*dēd* ‘deed’, *slēpa* ‘to sleep’, *jēr* ‘year’) (Ringe and Taylor 2014, 146–50; Campbell 1959, 50–51, §128). Old Saxon and Old High German keep the back vowel (Old Saxon *dād* ‘deed’, Old High German *tāt* ‘deed’, *slāfan* ‘to sleep’, *lāzan* ‘to let’), but sporadic Old Saxon spellings in $\bar{e}$ show that the fronting lapped unevenly into Old Saxon territory (Ringe and Taylor 2014, 150). The change is therefore a North Sea Germanic development rather than an exclusively Anglo-Frisian one, though only Old English and Old Frisian carry it through systematically.

The fronting affected stressed, non-nasalized $*\bar{a}$; nasalized $*\bar{q}$ was instead rounded, as treated in the rounding chapter. Ringe and Taylor further establish a conditioning by a following $*w$. Before $*w$ plus a back or non-high vowel the $*\bar{a}$ was retained: the clearest witnesses are the *verba pura* — *sāwan* ‘to sow’, *cnāwan* ‘to know’, *blāwan* ‘to blow’, *māwan* ‘to mow’, *brāwan* ‘to turn’ — together with *clāwu* ‘claw’ (Ringe and Taylor 2014, 151); the simplest hypothesis, which Ringe and Taylor adopt from Hogg, is that fronting never occurred in that environment (Ringe and Taylor 2014, 151; Hogg 1992a, 81). Before $*w$ plus a high front vocalic, by contrast, the fronting did apply: $*lēwijanq$ ‘to betray’ (Gothic *lēwjan* ‘to betray’, Old High German *gilāen* ‘to betray’) yields West Saxon *lēwan* ‘to betray’, and the same environment appears in *eltāwe* ‘entire’ and *brāw* ‘eyelid’ (Ringe and Taylor 2014, 150). Both sides of the condition are encoded in the rule below and witnessed in the corpus. Bennett states the retaining environment independently from the West Saxon evidence alone, and slightly more broadly: West Saxon “shows $\bar{a}$ as a regular isolative development of IE $\bar{e}$ but has $\bar{a}$ before w or g plus a back vowel”, with the paradigmatic alternation *wāg* ‘wave’ beside plural *wāgas* ‘waves’ (Bennett 1950, 235, n. 6). The rule below encodes the w environment, for which the corpus supplies witnesses on both sides; the parallel g environment is left for separate treatment.

Whether this fronting restored a front vowel that had earlier been backed, or whether — as Fulk argues — the North Sea dialects simply retained an old front $*\bar{a}$ that was never backed at all, is the same dispute recorded in the lowering chapter (Fulk 2018, 60–61, §4.6; Campbell 1959, 50–51, §§128–129). On the retention analysis this chapter’s change dissolves into the non-event of staying put; the present model follows Ringe and Taylor’s two-step reconstruction, on the strength of the runic evidence for an early [a:] and the place-adverbs *pær* ‘there’ and *hwær* ‘where’ (Ringe and Taylor 2014, 13–14).

32.2 SC101. Fronting of long $\bar{a}$ outside nasal and w environments (EAFLongAFronting)

```
define EAFLongAFronting [  
  { $\bar{a}$ } -> { $\bar{æ}$ } || _ [EnglishStarConsonant - EnglishStarNasal - { $*w$ }],  
  { $\bar{a}$ } -> { $\bar{æ}$ } || _ { $*w$ } EnglishIUmlautTrigger  
];
```

The first clause fronts $*\bar{a}$ before any oral consonant other than $*w$; the second admits the fronting before $*w$ exactly when a high front vocalic follows. The two corpus witnesses of the w condition form a minimal contrast. $*sēanq$ ‘to sow’, whose hiatus-filling w is supplied by SC102 EAFHiatusWInsertion, reaches this rule as $*sāwanq$ and is left unfronted, surfacing as *sāwan* ‘to sow’; were the w -block removed, the cascade would deliver $^{\dagger}sēwan$ instead. $*lēwijanq$ ‘to betray’, whose inherited w is followed by $*i$, is fronted by the second clause to $*lēwijanq$ at this rule’s own stage — before, and independently of, the much later i-umlaut — and surfaces as *lēwan* ‘to betray’. The rule consumes the $*\bar{a}$ created by SC024 PNWGmcLongELowering; displaced before the lowering, it has nothing to front, and $*skēpq$ ‘sheep’ surfaces as $^{\dagger}scāp$ rather than OE *scēap* ‘sheep’, $*jērq$ ‘year’ as $^{\dagger}gār$ rather than *gēar* ‘year’, $*slēpanq$ ‘to sleep’ as $^{\dagger}slāpan$ rather than *slāpan* ‘to sleep’.

Two later boundaries carry real historical content. First, the fronting must precede the completion of SC004 EAFaiMonophthongization: the *ā* that arose from **ai* was never fronted — *stān* ‘stone’, *hām* ‘home’, *lāp* ‘hostile’, *rāp* ‘rope’, *tācn* ‘token’, *gāst* ‘spirit’ all keep the back vowel. Campbell draws exactly this chronological inference (Campbell 1959, 52–53, §132), and Ringe and Taylor endorse it as cogent (Ringe and Taylor 2014, 169–70); in the present cascade the inference is enforced by rule order, and displacing the fronting after the monophthongization wrongly yields [†]*lāp*, [†]*rāp*, [†]*tācn*, [†]*sāwol*, and [†]*gēast*. Historically the two changes may well have overlapped in time; the discrete ordering is the grammar’s way of stating that inherited *ā* had been fronted before the new *ā* arose.

Second, the fronting must precede SC056 OEWSPalatalDiphthongization, which operated on the already-fronted vowel: *ē* > *ēa* after the palatals, as in *scēap* ‘sheep’ and *gēar* ‘year’ (Campbell 1959, 69–70, §185; Ringe and Taylor 2014, 215–16, §6.5.1). Displaced after the diphthongization, the cascade yields [†]*scāp* and [†]*gār* instead.

33 Anglo-Frisian ai-monophthongization

33.1 Historical discussion

Inherited stressed **ái* yields **ā* in English. Ringe and Taylor discuss this development separately from the earlier unstressed contraction. The distinction between inherited long vowels and new **ā* requires inherited-long fronting to have been well under way before contraction completed; it does not prove that the two developments could not overlap (Ringe and Taylor 2014, 170–71). Campbell gives the stricter conventional sequence and places contraction before ordinary short-vowel fronting (Campbell 1959, 52–53). Later i-mutation of the new long vowel is a separate conditioned development, not that ordinary fronting (Campbell 1959, 69).

Versloot proposes a wave account of the regional outcomes, but CAPR does not adopt diffusion as a solution to the comparative tree problem. His readings of early English and Frisian inscriptions are relevant evidence independently of that mechanism, conditional on their provenance, etymology and phonetic interpretation (Versloot 2017, 295–97, 318). The required Anglo-Frisian ancestral node is retained. Whether completed English contraction belongs after it is distinct from the possibility of an earlier conditioned onset on the common stem; the current operational corridor does not settle that question.

The live selected-corpus census has twenty-three applications, all carrying stressed **ái*. Loam's selected **láimq* 'loam' is explicitly a pre-Old-English model input, not an independent Proto-Germanic witness. The raw corpus's additional roe reconstruction has no attested target and is excluded from that census. The unstressed development **ai* > **ē* is the separate earlier change SC014 PNWGmcUnstressedAiMonophthongization.

33.2 SC004. Anglo-Frisian ai-monophthongization (EAFaiMonophthongization)

```
define EAFaiMonophthongization [  
  {*ái} -> {*ā}  
];
```

The soul form fixes the relation to interstress raising. If the monophthongization is delayed until after that change, PGmc **sáiwalo* 'soul' yields *†sāwel* rather than expected OE *sāwol* 'soul'. An earlier placement changes no output. This shows that SC004 EAFaiMonophthongization must come before SC036 OEInterStressRaising in the modeled sequence.

The unstressed development **ai* > **ē* in final and nonfinal syllables is a separate and earlier change; see SC014 PNWGmcUnstressedAiMonophthongization.

34 Chapter 4. From Anglo-Frisian to Old English

34.1 Historical interval

This chapter follows the English daughter from the required Anglo-Frisian ancestor through pre-historic English to attested Old English. It includes changes earlier than the manuscript period, not merely changes within it. West Saxon is the principal target; each comparison still requires its actual dialect, paradigm cell and evidential status.

34.2 Scope and dialect variation

Not every change in this chapter has pan-Old-English scope. Some changes — most notably ordinary West Saxon palatal diphthongization and parts of the back-mutation history — are specifically West Saxon or more broadly southern Old English phenomena. The diphthong corridor also represents earlier West Germanic feeders; a West Saxon final outcome does not date every feeder to West Saxon (Ringe and Taylor 2014, 41–42, 65–66, 171–73, 215–17). (The West Saxon palatal-glide spellings, SC016, belong to the written surface of Old English and are treated in Chapter 5.)

The CAPR derivations target West Saxon Old English citation forms as the default comparator. Changes that belong to other dialects, or that are absent from West Saxon, may appear in lexical entries as comparanda rather than as derivational steps.

The distinction between West Saxon and Anglian comparanda requires the actual text and dialect, not merely a regional label. Hogg discusses the limits of the traditional divisions and the evidence for the principal textual varieties (Hogg 1992a, 3–8, §§1.5–1.12).

34.3 Chapter structure

The changes in this chapter fall into several natural historical subgroups, though the boundaries between them are not always sharp:

Early Old English changes linked to the Anglo-Frisian inheritance: Changes that feed directly on, or are closely related to, Anglo-Frisian brightening (SC043), whose section opens the vowel corridor of this chapter. The **awj* resolution, **au* fronting and diphthong operations currently execute before ordinary-a brightening. They cannot be described as consuming its output. Their histories combine earlier glide reanalysis with English diphthong realization (Campbell 1959, 44–47; Ringe and Taylor 2014, 65–66, 171–73). The conventional breaking/restoration account instead presupposes fronted **æ*. English plain-a/au process identity and inherited stem identity remain separate questions.

Old English consonantal changes: Velar palatalization (SC052), palatalization of **sk* (SC051), j-cluster coalescence (SC057), and related changes produce the characteristically Old English consonant phonemes. Hogg discusses these as OE consonant changes with class-specific conditions and chronology (Hogg 1979, 90–111).

Old English i-umlaut and its context: The i-umlaut changes vowels under a following high front vocoid; paradigm alternations are evidence for that phonological conditioning, not grammatical conditions on the law (Campbell 1959, 69–72, §§190–197; Ringe and Taylor 2014, 222). Ordinary West Saxon palatal diphthongization precedes mutation in the handbook account, while the later treatment of some mutation products after *sc̥* follows it (Fulk 2018, 74; Campbell 1959, 68–69; Ringe and Taylor 2014, 215–17, 235). The adopted cascade now places the ordinary component before mutation and retains the late approximation afterward. Gift enters with the earlier-raised vowel, following Ringe's explicitly PGmc reconstruction (Ringe 2017, 135, pp. 151–153). Its lexical section discusses the published e-alternatives and the confidence in this choice.

Late Old English syllabic reduction and apocope: High-vowel apocope (SC063), medial syncope (SC065), and the cluster of late unstressed-vowel changes (SC069–SC078) represent the later stage of Old English phonological history, when the syllabic structure of the language began to shift toward the more reduced profile of Middle English.

34.4 The English partial chains

The working historical scaffold has several connected chains, not one uniquely demonstrated total order. Their evidential strength differs. An explicit handbook derivation, a contrast between original and secondary vowels, and the survival of a modeled output are not interchangeable arguments (Ringe and Taylor 2014, 170–73, 215–37; Hogg 1979, 100–110).

Historical relation	Evidence and interpretation	Limitation
Coronal assimilation before inherited ww reanalysis	Four and the second-person pronoun have assimilated inputs to vocalization	Does not date every j-created geminate
Inherited-long restructuring before completed ai contraction	New ai-derived long a escapes inherited-long fronting	Temporal overlap is possible
Completed ai contraction before ordinary short fronting	Conventional Campbell chain	Depends on the diphthong-nucleus premise
Ordinary fronting before breaking/restoration	Conventional English reconstruction	Never-fronted and restored outputs can coincide
Breaking before ordinary palatal diphthongization before mutation	Broken inputs and worked handbook vowel histories	Does not date every consonantal palatal layer
Mutation before the later sc treatment	Ai-derived mutation products such as sheath	Exact later conditioner remains unresolved
Initial productive palatal cutoff before mutation-created fronts	Unrounded mutation vowels are the stronger controls	Medial fricative merger is a separate problem

The first three relations are supported and qualified by the earlier vowel accounts (Ringe and Taylor 2014, 41–42, 65–66, 170–73; Campbell 1939, 90–91). The palatal and mutation relations require their own evidence (Luick 1914–1940, 162–63; Fulk 2018, 74; Ringe and Taylor 2014, 215–17, 235; Hogg 1979, 100–110). The table states the defended historical targets; it does not claim that every present executable proxy already realizes them faithfully.

34.5 Early glide history and the English outcome

The diphthong corridor includes inherited ww, assimilated ww and geminates created later before j. These inputs must be distinguished before assigning one date to their long-vowel outputs. Ringe and Taylor describe inherited glide reanalysis separately from the English realization of its products (Ringe and Taylor 2014, 41–42, 65–66, 171–73). The model currently telescopes parts of that history.

Witness	Earlier disputed checkpoint	Later English outcome	What it tests
Four	Assimilated ww can be reanalyzed as eu plus w	fēower ‘four’	Assimilation feeder and retained glide
Hew	Inherited a plus ww can give au plus w	hēawan ‘hew’	Reanalysis distinct from English realization
You	Vocalized iu plus w with a surviving final i before apocope	ēow ‘you’	Prosody/apocope compatibility, not merely quantity
Hue	Later j-gemination creates a distinct glide input	hīew ‘hue’	Negative control for the earlier inherited-ww subset

Witness	Earlier disputed checkpoint	Later English outcome	What it tests
Hay	Later awj history remains separate	hīeġ ‘hay’	Gemination and secondary glide resolution

These are intermediate questions rather than new corpus admissions. The current spelling differences also require their actual dialectal interpretation (Campbell 1959, 44–47; Ringe and Taylor 2014, 41–42, 57–58, 171–73). The reconstructed West Saxon *strew* target is a computational control, not an additional attested form.

An isolated early-reanalysis experiment exposes a genuine representation dependency. Once the first *w* is vocalized, the present apocope proxy no longer recognizes its consonantal-*ww* context in the pronoun. An explicitly technical recognition control restores its output, but that success does not make vocalized segments the historical condition for apocope. The source account depends on word-level stresslessness and early loss of the high vowel (Ringe and Taylor 2014, 41–42, 57–58). Any historical decomposition must account for that prosody instead of rejecting an early history because a later proxy expects another encoding.

34.6 Ordinary fronting, breaking and restoration

The preferred conventional account identifies ordinary non-nasal short-*a* fronting and fronting of *au*’s first element as one English episode. The later offglide development is distinct. Early spellings record the fronted element, but do not measure the simultaneity of two laws (Campbell 1939, 91; 1959, 52–53; Luick 1914–1940, 130–31). English episode identity is not inherited Anglo-Frisian event identity. Nor does it identify the stressed-short process with every unstressed or long-final clause in the present model.

Breaking then has vowel, quantity, consonantal and dialectal conditions. Restoration in a following back-vowel environment can remove a previously fronted vowel. A final restored vowel alone cannot distinguish that history from original blocking of fronting (Hogg 1979, 90–97; Versloot 2025, 104, 123). The conventional account is retained as the working baseline because of the combined argument, not because the more elaborate intermediate path is inherently preferable.

Versloot’s late Anglian alternatives must be compared in their exact domains. His mutation-created *e* argument and the unbroken neighboring environments are relevant to a restricted *e*-breaking component, not to a wholesale postmutation relocation of every West Saxon breaking law (Versloot 2025, 126–28, 131–35). A different dialectal target cannot be silently substituted for a West Saxon lexical target. Similarly, Frisian closed-syllable breaking is not English *rC* breaking merely because both are called breaking (Bremmer 2009, 33–35, 37).

34.7 Palatal consonants and the key–day problem

The useful chronological contrast is between original conditioning fronts and front vowels created by mutation. Rounded mutation products alone may support a weaker conclusion, a cutoff before later unrounding. Unrounded mutation-created fronts more directly test whether initial velar palatalization was still productive (Hogg 1979, 100–103; Laker 2007, 167–68). This cutoff does not by itself date assibilation or every earlier articulatory tendency.

Hogg’s key and day paradigms make the remaining problem explicit. The initial key consonant survives a mutation-created unrounded front vowel; the day paradigm does not show the mutation that would follow if its new medial palatal element were already equivalent to inherited *j*. These statements concern particular historical cells, not arbitrary exceptions to a sound law (Hogg 1979, 102–10).

Diagnostic	Required distinction	What is not established
Key oblique vowel	Original fronts versus mutation-created fronts	Date of all palatal articulation
Day oblique vowel	Inherited j versus a newly effective medial trigger	A proven delayed-merger solution
Geminate/postnasal g	Stop-class history versus singleton fricative	One universal g-to-j change
h	Breaking trigger versus subsequent palatal/weakening history	Identity with voiced-fricative chronology
sk	Own consonantal law versus later sc vowel treatment	A single combined palatalization event

Hogg considers several resolutions without endorsing one as demonstrated (Hogg 1979, 103–10). The unresolved merger question is therefore retained locally. Cluster coalescence and a dotted written reflex cannot be used to solve it by identifying different input consonants as one historical sound (Laker 2007, 167–68).

34.8 Three different mutation and diphthongization arguments

Guest, sheath and gift do not establish the same chronological relation. The guest derivation passes through ordinary palatal diphthongization before mutation in both the handbook account and the adopted model. The former model raised a simple vowel before diphthongizing it. Both paths reach *ġiest* ‘guest’, so their final agreement does not select the earlier path (Ringe and Taylor 2014, 216).

The following worked comparison abstracts from consonant notation and retains the vocalic trigger where it matters. For guest, the source starts with PGmc **gastiz* ‘guest’, continued as PWGmc **gasti* ‘guest’. The vowel history is **a* > **æ* > **ea* > **ie*; final loss of the trigger follows the mutation it caused (Ringe and Taylor 2014, 216, 287).

Checkpoint	Handbook and adopted guest path	Superseded modeled guest path
Ordinary fronting After palatal conditioning is established	Short a becomes æ Original front vowel is available to ordinary PD	Short a becomes æ Original front vowel is available, but PD remains later
First disputed vowel operation	æ becomes ea by ordinary PD	æ becomes e at mutation
Second disputed vowel operation	ea becomes ie at mutation	e becomes ie in the bundled PD proxy
Written result	ġiest ‘guest’	ġiest ‘guest’

The agreement in the last row is precisely why the intermediate rows must be tested. This table does not treat the implementation’s palatal-consonant symbol as proof of a uniquely dated phonetic merger (Hogg 1979, 103–10).

Witness	Source-supported distinction	Present model consequence
Guest	Ordinary palatal diphthongization feeds mutation	Adopted æ > ea > ie replaces the output-equivalent old path
Sheath	Ai-derived ā mutates; a later sc layer can affect its product	Its unchanged late clause is separately retained as an approximation

Witness	Source-supported distinction	Present model consequence
Gift	Earlier inherited e-to-i raising is distinct from English mutation	Selected PGmc i is outside ordinary diphthongization
Sheep/year	Ordinary palatal diphthongization without a mutation trigger	Controls for the ordinary component
Cow/lung	Mutation changes the productive consonantal environment	Controls for cutoff, not diphthongal mutation

For sheath, *scēap* ‘sheath’ beside *scæp* ‘sheath’ belongs to the separately described later group. Reporting both outcomes does not authorize lexical optionality in the law; the exact phonological layer and conditioner still require a defended specification (Campbell 1959, 68–69; Ringe and Taylor 2014, 235). The incremental repair preserves the literal late clause as a visible approximation, not a lexical exception or a newly established conditioner.

The sheath comparison instead follows the ai-derived long vowel: **ai* > **ā* > **ǣ*, with the final step supplied by mutation. The separately discussed later *sc* treatment can then give **ēa*. The vowel available to the earlier ordinary process and the vowel created later by mutation are therefore different historical inputs, which the adopted model now separates (Campbell 1959, 68–69; Ringe and Taylor 2014, 235).

For gift, Ringe reconstructs PGmc **giftiz* ‘gift’, with the Old English plural *gifta* ‘wedding’, and describes the earlier raising separately (Ringe 2017, 135, pp. 151–153). Ringe and Taylor explicitly distinguish that early change from the much later English vowel history (Ringe and Taylor 2014, 220). The selected input now follows that earlier-raised reconstruction. The choice is lexical and source-led, not a new raising rule justified by output fit. Orel and Kluge–Seebold print e-vowel alternatives (Orel 2003, 130; Kluge 2011, 359); the lexical section compares their evidence with the e-grade presentations and Ringe’s qualified PGmc dating rather than claiming unanimous agreement.

34.9 Quantity, reduction and the written surface

Later apocope and syncope depend on prosody and syllable structure; earlier input conventions and surviving triggers must be inspected before their effects are used as dates for other changes. Morphological cells provide evidence for such environments, not grammatical conditions on phonological rules (Ringe and Taylor 2014, 57–59, 299–300). Inherited quantity, compensatory lengthening, diphthong quantity and later shortening must likewise remain separate dimensions.

The transition to Chapter 5 is a transition to the written surface, not proof that an orthographic change is a newly dated sound change. A single spelling can represent different historical consonant inputs, and a changed spelling need not change the phonetic derivation. The source discussions and worked lexical entries distinguish implemented laws from working reconstructions and localized unresolved components.

34.10 Executable serialization and unresolved interfaces

Sections follow executable order to make derivations inspectable, not because that serialization proves a unique total history. Final agreement can conceal different intermediate paths. Some proxies execute here with earlier historical classifications; renaming identifiers would not resolve that substantive distinction:

- SC041 (PWGmc Final Bare-**a* Loss) and SC042 (Surviving Bimoric **ō* Unrounding) carry Proto-West Germanic labels but execute in this stretch of the cascade.
- SC064 (NWGmc **-n* Stem **n* Loss) carries a Northwest Germanic label but executes after OE High-Vowel Apocope (SC063).

- SC049 (PGmc B Allophony) carries a Proto-Germanic label but executes here.

34.11 Sources

Campbell's *Old English Grammar* is the primary source for the dating and scope of individual changes in this chapter (Campbell 1959, 52–72). Hogg provides critical reassessments of palatal conditioning and its relative chronology (Hogg 1979, 90–112). Ringe and Taylor supply the most detailed relative-chronology analysis for the earlier portion of the chapter, through back-mutation (Ringe and Taylor 2014, 169–73, 215–37). Fulk's *Comparative Grammar* provides additional coverage for phonological conditioning (Fulk 2018, 58–61, 72–74). For individual changes, source-specific citations appear in the relevant sound-change sections.

35 Awj resolution and the English brightening of au

35.1 Historical discussion

Two changes stand between the Proto-Germanic diphthong **au* and its Old English reflex *ēa*. The earlier one repairs a West Germanic gemination and restores a diphthong that the gemination had obscured. The later one fronts the first element of every **au*, whether inherited or newly created, and belongs with Anglo-Frisian brightening.

The two are separate developments with separate domains. The first concerns a handful of words in which **w* stood before **j*. The second concerns the whole Old English history of **au*, for which *lēaf* 'leaf', *strēam* 'stream' and *brēad* 'bread' are ordinary witnesses, and to which the first change merely adds two more inputs.

35.2 Historical discussion of the resolution of **awj*

Old English *hīeg* 'hay' and *strīegan* 'strew' go back to forms in which **w* preceded **j*. West Germanic doubled every consonant except **r* before **j* after a short syllable, and **w* was an ordinary member of that law (Campbell 1959, 167, §407). Proto-Germanic **hawja-* therefore appears as West Germanic **hauuj* (Campbell 1959, 46, §120.2). Campbell writes the sequence as *auj* > *auuj* > *auj*, with the diphthong restored before the Old English developments begin.

Ringe and Taylor reach the same result and explain why it is possible (Ringe and Taylor 2014, 53, §3.1.3). They find the gemination of **wj* clearest where the preceding vowel was **i*, as in Proto-Germanic **niwjaz* 'new' and **siwjana* 'sew', which give Old Saxon and Old High German *niuwi* and *siuwen*. Gemination was reversible, since it merged nothing and altered no underlying form, so the sequence Northwest Germanic **awj* to West Germanic **[aw'w']* to pre-Old English **[auj]* can have run its course and then undone itself. Their derivations give Proto-Germanic **hawja* through **hauj-* to *hīeg* 'hay', and Proto-Germanic **strawjana* through **straujan* to Anglian *strēgan* 'strew' (Ringe and Taylor 2014, 173).

The strongest comparative argument for the doubled stage comes from paradigms in which some cells had **j* in the ending and others had **i*. Only the first group could double, and the two outcomes then sat side by side. Old High German has *hewi* 'hay' beside *houwi*, and Old English itself preserves both in one word, *glīg* 'mirth' from the undoubled nominative beside *glīowes* 'of mirth' in the genitive (Ringe and Taylor 2014, 53, §3.1.3). The continental forms *houwi* and *gistrōuwen* 'bestrew', and Old Saxon *hoi* 'hay', point to the same West Germanic stage, which English alone went on to resolve (Ringe and Taylor 2014, 173).

The resolution did not treat every doubled **w* alike, and the difference is what allows the doubling to be seen apart from it. Campbell sets the two vowel types side by side: *auj* becomes *auuj* and then *auj*, while *iuj* becomes *iuuj* and then *iuj*. Thereafter they part company, since the *u* of *auuj* is generally lost while the *j* of *iuuj* is lost (Campbell 1959, 46, §120.2). Old English *hīeg* 'hay' and *hīew* 'form, hue' begin from shapes that differ in a single vowel and end with different survivors. *Hīeg* keeps its **j*, written *ġ*, while *hīew* keeps its **w*. Campbell's other examples of the second type are *nīowe* 'new', *nīewe* 'new' and *glīow* 'mirth', *glīw* 'mirth'.

One qualification belongs in the record. Fulk holds that **w* was never consonantal here, so that Proto-Germanic already had **straujaną* with its diphthong in place and there is no gemination to undo (Fulk 2018, 73, §4.10 n. 1). The account followed here is the handbook one, which the comparative material supports: the doubled stage that the continental and paradigm-internal forms point to is precisely the one Fulk denies ever existed. Both accounts agree that **auj* is what enters Old English, and the disagreement concerns whether a discrete change took place.

35.3 SC029. Resolution of **awj* to **auj* (OEAwjResolution)

```
define OEAwjResolution [
  {*á} {*w} {*w} {*j} -> {*áu} {*j},
  {*a} {*w} {*w} {*j} -> {*au} {*j}
];
```

The change is confined to the **a* type. PGmc **xáwją* ‘hay’ is doubled to **xáwwją* by the West Germanic law and then resolved to **xáuja*, and PGmc **stráwją* ‘strew’ is doubled to **stráwwjaną* and resolved to **stráujaną*, yielding *hīeg* ‘hay’ and *strīegan* ‘strew’ once the later diphthong changes and *i*-umlaut have applied. PGmc **xéwją* ‘form, hue’ is doubled by the same law, and there the doubling holds: it passes through this change untouched and surfaces as *hīew* ‘form, hue’.

The resolution has to precede SC030 OEAuBrightening, since the fronting needs a diphthong to work on. Ringe and Taylor state the same dependence when they observe that these new instances of **au* went on to share the ordinary development (Ringe and Taylor 2014, 173).

35.4 Historical discussion of the brightening of **au*

The fronting of **au* is the application to a diphthong of the same process that fronts plain **a*, the process usually called Anglo-Frisian brightening. Campbell arrives at the point while establishing the order of the early vowel changes, remarking that the normal development of Proto-Germanic **au* to Old English *ēa* shows that the change of *a* to *æ* would affect the first element of a diphthong (Campbell 1959, 52, §132). His ordered list accordingly places West Germanic *a* > Old English *æ* and West Germanic **au* > Old English **æu* in one and the same step. Fulk puts it in a single sentence, saying that this fronting of *a* applied also to the diphthong *au* in Old English (Fulk 2018, 73, §4.12).

The intermediate stage is directly attested. Ringe and Taylor describe **au* as first tensed and fronted to **æu*, a spelling still found occasionally in eighth-century documents, with the offglide unrounded and lowered only later (Ringe and Taylor 2014, 172). Early spellings such as *Eadbald* with an initial *aeo* preserve the rounded offglide, and the rounding survives in late Northumbrian (Fulk 2018, 73, §4.12). The outcome of the whole sequence is the *ēa* of *dēap* ‘death’, *ēage* ‘eye’ and *lēaf* ‘leaf’ (Campbell 1959, 53, §135).

The geographical reach of the diphthongal fronting is narrower than that of the plain one. Old Frisian shows no such fronting and has *ā*, so that Old English *ēac* ‘also’, *ēage* ‘eye’ and *bēam* ‘tree’ stand against Old Frisian *āk* ‘also’, *āge* ‘eye’ and *bām* ‘tree’ (Fulk 2018, 73, §4.12; Ringe and Taylor 2014, 172). A later change supplies independent confirmation. Old English *gēac* ‘cuckoo’ has a palatalized initial, which requires a front vowel to have followed it, while Old Frisian *gāk* ‘cuckoo’ has none (Fulk 2018, 73, §4.12). Brightening of plain **a* is shared with Frisian; brightening of the first element of **au* is English.

35.5 SC030. Brightening of **au* to **æu* (OEAuBrightening)

```
define OEAuBrightening [
  {*au} -> {*æu},
  {*áu} -> {*áu}
];
```

Most of the words that pass through the change carry **au* inherited straight from Proto-Germanic. PGmc **láubq* ‘leaf’ gives *lēaf* ‘leaf’, PGmc **stráumaz* ‘stream’ gives *strēam* ‘stream’, PGmc **bráudq* ‘bread’ gives *brēad* ‘bread’, and PGmc **dráugmaz* ‘dream’ gives *drēam* ‘dream’. Where a following **j* or **i* survives long enough to cause *i*-umlaut, the *ēa* appears in West Saxon as *īe*, as in *ġeliefan* ‘believe’ from PGmc **galáubijanq* ‘believe’ and *nīed* ‘need’ from PGmc **náudiz* ‘need’ (Campbell 1959, 46, §120.2). The two words supplied by SC029 OEAwjResolution, *hīeg* ‘hay’ and *strīegan* ‘strew’, join this second group.

The proportions matter for what the rule is. This is the general Old English treatment of **au*, to which the resolution of **awj* contributes two further inputs; the history of *hīeg* ‘hay’ and *strīegan* ‘strew’ does not define it.

The fronted **æu* has no independent life. It is taken up at once by the SC032 OEDiphthongLeveling, which lowers the offglide and delivers *ēa*. Ringe and Taylor give that order explicitly when they place the tensing and fronting first and the unrounding and lowering later (Ringe and Taylor 2014, 172).

36 Long ēow before following vowels

36.1 Historical discussion

Four distinct developments shape the West Saxon diphthongal field. Campbell discusses inherited *aw/ew* outcomes, palatal-triggered diphthongization, and later Anglian smoothing in connected but separate parts of the vowel history; Hogg likewise distinguishes the palatal-diphthongal developments (Campbell 1959, 46, 53–54, 65–70, 95–96, §§120, 135–136, 170–176, 185, 223–227; Hogg 1992b, 112–13).

The closest interaction joins *ww*-simplification and long-*aw* diphthongization, which together shape *dēaw* ‘dew’ and *hēawan* ‘hew’. Diphthong leveling regularizes a wider field, while long-*ew* diphthongization carries *ēow* into the later environment of breaking.

The long *ēow* forms of *cēowan* ‘chew’, *fēower* ‘four’, and *cnēow* ‘knee’ form part of the West Saxon vowel history, although their clearest ordering relation points forward. Campbell describes early *eu* in Old English, and Ringe and Taylor give the corresponding examples from chew, four, and knee (Campbell 1959, 53–54, §136; Ringe and Taylor 2014, 188, 202).

The only boundary established by the lexical evidence for SC033 OEEwLongDiphthong lies ahead at SC044 OEBreaking.

36.2 SC033. Long ēow before following vowels and weak endings (OEEwLongDiphthong)

```
define OEEwLongDiphthong [  
  {*e} {*w} -> {*ēo} {*w} || _ OEEwLongContext,  
  {*i} {*w} -> {*ēo} {*w} || _ OEEwLongContext,  
  {*é} {*w} -> {*ēo} {*w} || _ OEEwLongContext,  
  {*ī} {*w} -> {*ēo} {*w} || _ OEEwLongContext  
];
```

The long *ēow* of *cēowan* ‘chew’, *fēower* ‘four’, and *cnēow* ‘knee’ supplies only a terminus ante quem. If SC033 OEEwLongDiphthong follows SC044 OEBreaking, PGmc **kéwwanq* ‘chew’ yields [†]*cēowan* rather than expected OE *cēowan* ‘chew’, PGmc **fédwōr* ‘four’ yields [†]*feower* rather than expected *fēower* ‘four’, and PGmc **knéwq* ‘knee’ yields [†]*cneow* rather than expected *cnēow* ‘knee’. Earlier placement changes no output. The sources associate *ew* and *iw* with the same diphthongal history but furnish no lower boundary.

37 Simplification of **ww* sequences

37.1 Historical discussion

West Germanic *ww* sequences lie behind forms such as *dēaw* ‘dew’ and *hēawan* ‘hew’, and Campbell treats them as part of the early West Germanic diphthong history (Campbell 1959, 46, §120).

SC031 OEWWsimplification precedes the later long-diphthong outcomes.

37.2 SC031. Simplification of **ww* sequences (OEWWsimplification)

```
define OEWWsimplification [  
  {*w} {*w} -> {*w}  
];
```

The *dēaw* ‘dew’ and *hēawan* ‘hew’ derivations establish that doubled *w* was simplified before the long *ēaw* development. If SC031 OEWWsimplification follows SC034 OEAwLongDiphthong, PGmc **dāwwō* ‘dew’ yields [†]*dawu* rather than expected OE *dēaw* ‘dew’, and PGmc **xāwwaną* ‘hew’ yields [†]*hawan* rather than expected *hēawan* ‘hew’. Earlier placement changes no output. The witnesses require simplification before the long-diphthong change and leave the lower boundary to the broader West Saxon chronology.

38 Leveling of diphthongal outputs

38.1 Historical discussion

Forms such as *hēafod* ‘head’ reflect the redistribution of diphthongal outcomes across a wider set of words. Campbell describes smoothing and related later monophthongization, although the rule below is more narrowly conditioned than any single textbook label (Campbell 1959, 95–96, §§223–227).

The evidence for SC032 OEDiphthongLeveling is less self-contained than that for the *dēaw* ‘dew’ / *hēawan* ‘hew’ developments.

38.2 SC032. Leveling of diphthongal outputs (OEDiphthongLeveling)

```
define OEDiphthongLeveling [  
  {*aeu} -> {*ēa},  
  {*áeu} -> {*ēa},  
  {*eu} -> {*ēo},  
  {*éu} -> {*ēo},  
  {*iu} -> {*ēo},  
  {*íu} -> {*ēo},  
  {*e} {*u} -> {*eo},  
  {*é} {*u} -> {*éo},  
  {*i} {*u} -> {*eo}  
];
```

The two edges of this interval fail differently. Before SC030 OEaUBrightening, PGmc **galáubijanq* ‘believe’, **báug* ‘bow’, and **bráudq* ‘bread’ produce no output (+?) instead of expected OE *gēliefan* ‘believe’, *bēag* ‘bow’, and *brēad* ‘bread’, alongside fifteen other failed derivations. After SC040 OEmedUnstressedULowering, PGmc **xáubudq* ‘head’ yields [†]*hēafud* rather than expected *hēafod* ‘head’. Absence at the lower edge places diphthong leveling after fronting; the wrong surface form at the upper edge places it before medial unstressed-*u* lowering.

39 Long *ēaw* before following vowels

39.1 Historical discussion

After SC031 OEWWsimplification has reduced *ww* to single *w*, the remaining *aw* sequence can develop into the long *ēaw* seen in *dēaw* ‘dew’ and *hēawan* ‘hew’. Campbell treats these outputs in the early diphthong history of West Germanic and Old English (Campbell 1959, 46, 53–54, §§120, 135–136). The resulting long diphthong is *ēaw*.

SC034 OEAwLongDiphthong follows SC031 OEWWsimplification locally and must also precede SC043 EAFBrightening.

39.2 SC034. Long *ēaw* before following vowels (OEAwLongDiphthong)

```
define OEAwLongDiphthong [  
  {*a} {*w} -> {*ēa} {*w} || _ [EnglishStarVocalic | {*ō}],  
  {*á} {*w} -> {*ēá} {*w} || _ [EnglishStarVocalic | {*ō}]  
];
```

A local feeding relation and a later vowel change confine *aw* > *ēaw*. Before SC031 OEWWsimplification, PGmc **dāwwō* ‘dew’ yields *†dawu* rather than expected OE *dēaw* ‘dew’, and PGmc **xáwwanq* ‘hew’ yields *†hawan* rather than expected *hēawan* ‘hew’. After SC043 EAFBrightening, PGmc **skāwōjanq* ‘show’ yields *†scawian* rather than expected OE *scēawian* ‘show’, PGmc **skāwōθi* ‘shows’ yields *†scawaþ* rather than expected *scēawaþ* ‘shows’, and PGmc **strāwq* ‘straw’ yields *†stræw* rather than expected *strēaw* ‘straw’. The *dēaw* and *hēawan* forms require long-diphthong formation after simplification, while *scēawian* requires it before brightening; the handbooks assign the same interval to the West Saxon development.

40 Prefix and compound adjustments

40.1 Historical discussion of prefixal **a*-reduction

Weakly stressed prefixes can lose their older low vowel early in Old English, and that is the historical setting for SC035 OEPrefixAReduction. Campbell treats the small class of pretonic losses directly, while Ringe and Taylor's derivation of **galaubijana* 'believe' supplies the comparative witness for the same development (Campbell 1959, 147, §354; Ringe and Taylor 2014, 245; 2014, 267).

The rule has a narrow historical range and gives prefixed forms the weak vowel inherited by later vocalic changes.

40.2 SC035. Reduction of prefixal **a* (OEPrefixAReduction)

```
define OEPrefixAReduction [  
  {*a} -> {*ë}  
  || .#. {*g} _  
    [EnglishStarConsonant | EnglishPalatalConsonant]  
    EnglishStarVocalic  
];
```

The prefix of *ġeliefan* 'believe' supplies the upper boundary for **ga-* > **ge-*. If SC035 OEPrefixAReduction follows SC043 EAFBrightening, PGmc **galáubijanā* 'believe' yields *†ġealtiefan* rather than expected OE *ġeliefan* 'believe'. Earlier placement changes no output, so the witness dates prefix reduction before brightening without locating its beginning.

40.3 Historical discussion of inter-stress raising

SC036 OEInterStressRaising has the strongest evidence of the three. Campbell's discussion of *weorold* 'world' / *weoruld* 'world' and Ringe and Taylor's derivation of **weraldu* 'world' > **weruldu* 'world' > OE *weorold* place the rule squarely in the history of low-stress medial vowels (Campbell 1959, 141–42, §§338–339; Ringe and Taylor 2014, 322, §6.3.3).

The rule changes the vowel between stronger stress peaks, and its witnesses consequently constrain the relative chronology.

40.4 SC036. Raising of medial **a* between stress peaks (OEInterStressRaising)

```
define OEInterStressRaising [  
  {*a} -> {*u}  
  || PGmcStarVowel EnglishStarConsonant*  
    [EnglishStarConsonant - {*j}]+ [{*u}][{*ū}],  
  {*à} -> {*u}  
];
```

The two boundaries have unequal force. Before SC019 PNWGMcFinalLongORaising, PGmc **sái-walō* 'soul' yields *†sāwel* rather than expected OE *sāwol* 'soul'; after SC040 OEmedUnstressedU-Lowering, it yields *†sāwul* rather than *sāwol*, while PGmc **wír-àldu* 'world' yields *†weoruld* rather than *weorold* 'world'. The distant lower boundary places inter-stress raising after final long-*o* raising, and the local upper boundary places it before medial unstressed-*u* lowering. In hand-book terms, medial **a* > **u* belongs to the *world*- and *soul*-type low-stress vocalism that followed the earlier final-vowel changes.

40.5 Historical discussion of compound linking syncope

Compound members with weakened force often lose or reshape their linking vowels, and Campbell treats that broad pattern through reduced second elements, connecting vowels, and obscured compounds (Campbell 1959, 148–49, §§356–357; Campbell 1959, 153, §367; Campbell 1959, 159, §§386–387).

SC037 `OECompoundLinkingSyncope` captures this pattern in compounds such as *reǵnboga* ‘rainbow’. The only boundary the lexical evidence supplies is the immediately following technical stress-stripping stage, which is not a sound change.

40.6 SC037. Syncope of compound linking vowels (`OECompoundLinkingSyncope`)

```
define OECompoundLinkingSyncope [  
  [{*a}|{*i}|{*u}] -> 0  
  || PGmcStarAcuteVowel OEAnyConsonant+ _  
  OEAnyConsonant+ PGmcStarGraveVowel  
];
```

The *reǵnboga* ‘rainbow’ test exposes a bookkeeping dependency rather than a historical sound-change boundary. After SC038 `OEStripSecondaryStress`, PGmc **régna-bùgô* ‘rainbow’ yields *†reǵnefoga* rather than expected OE *reǵnboga* ‘rainbow’, because the technical stage has erased the stress information that licenses syncope. The handbooks instead place weakened compound junctures with the behavior described under SC035 `OEPrefixAReduction` and SC036 `OEInterStressRaising`.

41 Medial unstressed vowel changes

41.1 Historical discussion

The history of *wuduwe* ‘widow’ orders these two changes within the same low-stress vocalic development. Campbell discusses both the *w*-conditioned *u* forms and the later *weorold* ‘world’ / *weoruld* ‘world’ alternation, while Ringe and Taylor give the same connection comparatively in **widuwon-*, **weraldu* ‘world’, and **jugunþi* ‘youth’ (Campbell 1959, 92, §218; Campbell 1959, 140, §332; Campbell 1959, 141–42, §§338–339; Ringe and Taylor 2014, 267; Ringe and Taylor 2014, 322, §6.3.3).

SC039 OEWICombinativeUUmlaut feeds the vowel sequence subsequently reshaped by SC040 OEMedUnstressedULowering. Initial *w* conditions the first change.

41.2 SC039. Combinative **u*-umlaut in *wi*-forms (OEWICombinativeUUmlaut)

```
define OEWICombinativeUUmlaut [  
  {*i} -> {*ú}  
  || .#. {*w} _ EnglishStarConsonant [{*u} | {*o}]  
];
```

The *wuduwe* ‘widow’ derivation answers one narrow question about *wi*-forms. If SC039 OEWICombinativeUUmlaut follows SC040 OEMedUnstressedULowering, PGmc **wíduwōn* ‘widow’ yields [†]*wudowe* rather than expected OE *wuduwe*; earlier placement changes no output. The witness requires combinative u-umlaut to precede medial lowering and supplies no lower boundary.

41.3 SC040. Lowering of medial unstressed **u* (OEMedUnstressedULowering)

```
define OEMedUnstressedULowering [  
  {*u} -> {*o}  
  || [EnglishStarVocalic - [{*u}|{*ū}|{*ú}]]  
  [EnglishStarConsonant | EnglishPalatalConsonant]+ _  
  [[EnglishStarConsonant | EnglishPalatalConsonant] - {*m}]  
];
```

The two witnesses date medial unstressed **u* > **o* at very different scales. Before SC039 OEWICombinativeUUmlaut, PGmc **wíduwōn* ‘widow’ yields [†]*wudowe* rather than expected OE *wuduwe* ‘widow’; after SC072 OEUnstressedLongVowelShortening, PGmc **júgunθ* ‘youth’ yields [†]*ġeogop* rather than expected *ġeogup* ‘youth’. The local *weorold* ‘world’ and widow evidence places lowering after combinative u-umlaut, while the youth form supplies only the distant requirement that lowering precede unstressed long-vowel shortening.

42 Final bare-*a* loss

42.1 Historical discussion

I isolate the loss of final short low vowels within the broader erosion of final syllables described by the handbooks (Campbell 1959, 143, §341; Ringe and Taylor 2014, 60–61).

Final bare-*a* loss follows the medial unstressed vowel changes and precedes restoration, which depends on the environment left by the loss.

42.2 SC041. Loss of final bare **a* (PWGmcFinalBareALoss)

```
define PWGmcFinalBareALoss [  
  {*a} -> 0 || _ .#.  
];
```

The two sides of final bare-*a* loss rest on different evidence. Applied before final *z*-deletion, the change gives the wrong outputs: PGmc **bárdaz* ‘beard’ yields [†]*bearda* rather than expected OE *beard* ‘beard’, and PGmc **kámbaz* ‘comb’ yields [†]*camba* rather than expected *camb* ‘comb’. Applied after restoration, PGmc **kráftaz* ‘craft’ yields [†]*craft* rather than expected OE *cræft* ‘craft’, and PGmc **dágaz* ‘day’ yields [†]*dag* rather than expected *dæg* ‘day’. The distant lower limit follows final *z*-loss; the local feeding relation precedes restoration, which requires the environment created by the vowel loss.

43 Surviving bimoric * $\bar{o}$ unrounding

43.1 Historical discussion

The handbooks do not isolate a large independent sound change under this label. The surviving bimoric * $\bar{o}$ in the pathway to *ræste* ‘rest’ nevertheless undergoes unrounding before SC043 EAFBrightening. Campbell, Hogg, and Ringe and Taylor describe the surrounding fronting and restoration history without naming this feeder separately (Campbell 1959, 52, 60, §§131, 157–158; Hogg 1992b, 102, 105; Ringe and Taylor 2014, 157–58, 189–90).

The sole witness establishes a local relation to brightening but supports no broader generalization.

43.2 SC042. Unrounding of the surviving bimoric * $\bar{o}$ (PWGmcSurvivingBimoricOUnrounding)

```
define PWGmcSurvivingBimoricOUnrounding [  
  {*\bar{o}} -> {*\bar{a}} || EnglishStarVocalic [EnglishStarConsonant |  
    ↪ EnglishPalatalConsonant]+ _ .#.  
];
```

The single *ræste* ‘rest’ derivation carries the chronology of bimoric * $\bar{o}$ > * $\bar{a}$. Before SC020 EAFFinalZDeletion or after SC043 EAFBrightening, PGmc **rástōz* ‘rest’ yields [†]*rasta* rather than expected OE *ræste*. Unrounding must therefore follow final z-loss and precede brightening, although only the relation to brightening is local.

44 Anglo-Frisian brightening

44.1 Historical discussion

Anglo-Frisian Brightening or First Fronting turns low **a* into fronted **æ*-type outcomes outside nasal environments. Later Old English developments presuppose this fronted stage even where they partly conceal it. Campbell gives the classical statement of the change, Hogg supplies the standard modern labels, and Ringe and Taylor establish its local chronology with breaking and restoration (Campbell 1959, 52, §131; Hogg 1992b, 102, 105; Ringe and Taylor 2014, 157–58, 189–90; Fulk 2018, 73–74, §§4.12–4.13).

Brightening creates the input to SC044 OEBreaking, while SC046 OEARestoration later partly reverses its outcome before back vowels.

The traditional name does not itself establish one inherited event. Under Campbell’s premise that the daughter contractions precede ordinary fronting, comparable English and Frisian outcomes require separate daughter frontings in the strict tree. Chapter 3 develops that conditional argument without removing the ancestral node (Campbell 1939, 90–91). The present network also contains unstressed-short and long-final components; evidence dating stressed-short fronting does not automatically date those other clauses. The current computational control is retained while their historical identity is assessed separately.

44.2 SC043. Fronting of low **a* outside nasal environments (EAFBrightening)

```
define EAFBrightening [  
  AngloFrisianBrighteningUnstressed .o.  
  AngloFrisianBrighteningStressed .o.  
  AngloFrisianBrighteningLongFinal  
];
```

Two derivations place low **a* > **æ* between unrounding and breaking. Before SC042 PWGmc-SurvivingBimoricOUnrounding, PGmc **rástōz* ‘rest’ yields *†rasta* rather than expected OE *ræste* ‘rest’. After SC044 OEBreaking, PGmc **sláxanq* ‘slay’ yields *sleaan* | *slēaan* rather than expected OE *slēan* ‘slay’. The first witness requires brightening to receive the outcome of the surviving-bimoric **ō* development; the second requires breaking to receive the fronted vowel.

45 Breaking and velar-fricative palatalization

45.1 Historical discussion

Breaking creates *eo*-type outputs before *h*, *rC*, and *lC*; velar-fricative palatalization then operates in that reshaped environment. Campbell, Ringe and Taylor, and Fulk place breaking after brightening. The following fricative palatalization is more narrowly conditioned (Campbell 1959, 54, 166, §§139, 405–406; Ringe and Taylor 2014, 168–69, 213–14, §§6.2.1–6.2.3, 6.4.1–6.4.2; Fulk 2018, 73–74, §4.13).

Breaking has the fuller handbook treatment, while velar-fricative palatalization follows it locally in the *feoh* ‘cattle’ and *feohtan* ‘fight’ type derivations.

45.2 SC044. Breaking before *h*, *rC*, and *lC* (OEBreaking)

```
define OEBreaking OEBreakingA
  .o. OEBreakingE
  .o. OEBreakingI;
```

Breaking must encounter the vowel created by brightening and must precede the fricative change seen in *feoh* ‘fee’ and *feohtan* ‘fight’. Before SC043 EAFBrightening, PGmc **sláxanq* ‘slay’ yields *sleaan* | *slēaan* rather than expected OE *slēan* ‘slay’. After SC045 OEVelarFricativePalatalization, PGmc **féxu* ‘cattle’ yields *†fehu* rather than expected OE *feoh*, and PGmc **féxtanq* ‘fight’ yields *†fehtan* rather than expected *feohtan*. The two feeding relations place breaking between brightening and velar-fricative palatalization.

45.3 SC045. Palatalization of velar fricatives beside front vowels (OEVelarFricativePalatalization)

```
define OEVelarFricativePalatalization [
  {*x} -> {*ç} || _ EnglishStarFrontVowel,
  {*y} -> {*j} || _ EnglishStarFrontVowel,
  {*x} -> {*ç} || EnglishStarFrontVowel _,
  {*y} -> {*j} || EnglishStarFrontVowel _,
  {*x} -> {*ç} || _ {*j},
  {*y} -> {*j} || _ {*j}
]
.o. EnglishStarAlphabet*;
```

The local chronology comes from *feoh* ‘cattle’ and *feohtan* ‘fight’. Before SC044 OEBreaking, palatalization of **x* and **y* beside front vowels or **j* makes PGmc **féxu* ‘cattle’ yield *†fehu* rather than expected OE *feoh*, and PGmc **féxtanq* ‘fight’ yield *†fehtan* rather than expected *feohtan*. The distant upper limit comes from *six* ‘six’: after SC060 OEWsPalatalUmlaut, PGmc **séxs* ‘six’ yields *†sihs* rather than expected OE *six*. Breaking therefore feeds velar-fricative palatalization directly, while palatal umlaut supplies only the broader upper limit.

46 A-restoration and nasal changes

46.1 Historical discussion of A-restoration

Campbell's restoration of *a* before following back vowels and Ringe and Taylor's later retraction describe the same post-brightening development (Campbell 1959, 60–61, §§157–159; Ringe and Taylor 2014, 189–90, §6.3.1; Fulk 2018, 74, §4.13). Some outcomes of Anglo-Frisian fronting survive only in environments where restoration does not return them to back *a*.

SC046 OEARestoration has firmer handbook support than the two following nasal rules.

46.2 SC046. Restoration of **a* before following back vowels (OEARestoration)

```
define OEARestoration (
  { *æ } -> { *a } || _
    OEARestorationIntervening OEARestorationTriggerVowel
  - OEARestorationIntervening OEARestorationWeakTailVowel
);
```

Restoration must receive fronted **æ* and return **a* before the nasal-tail changes. Before SC043 EAFBrightening, PGmc **bákanq* 'bake' yields [†]*bæcan* rather than expected OE *bacan* 'bake', and PGmc **fáranq* 'fare' yields [†]*færan* rather than expected *faran* 'fare'. After SC048 OESecondaryNasalization, **bákanq* again yields [†]*bæcan* instead of *bacan*, while PGmc **wádanq* 'wade' yields [†]*wædan* instead of *wadan* 'wade'. These independent witness pairs place restoration after brightening and before secondary nasalization.

46.3 Historical discussion of heavy-syllable nasal loss and secondary nasalization

Heavy-syllable nasal apocope removes the final nasalized vowel; secondary nasalization then marks the preceding *a* before final *n*. The handbooks do not isolate both developments under equally prominent labels. Campbell describes later nasal loss and the back-mutation environment; Ringe and Taylor provide the later relation to back mutation (Campbell 1959, 86, 166, §§205–206, 403; Ringe and Taylor 2014, 319, §6.9.4).

The reciprocal failure set fixes the order: apocope removes the ending before secondary nasalization acts on the remaining structure. Restoration receives the fuller historical treatment in the handbooks.

46.4 SC047. Heavy-syllable nasal apocope of final **q* (OEHeavySyllableNasalApocope)

```
define OEHeavySyllableNasalApocope [
  { *q } -> Ø || OEAnyConsonant _ .#.
];
```

The evidence for final nasalized **q* loss is sharply asymmetric. Before SC034 OEAwLongDiphthong, the single PGmc witness **stráwq* 'straw' yields [†]*stræw* rather than expected OE *strēaw* 'straw'. After SC048 OESecondaryNasalization, PGmc **bákanq* 'bake' yields [†]*bacen* rather than expected OE *bacan* 'bake', and PGmc **bīdanq* 'bind' yields [†]*bīden* rather than expected *bindan* 'bind', alongside a broad *-en* failure set. One lower witness places apocope after long-diphthong formation; many reciprocal upper failures place it before secondary nasalization.

46.5 SC048. Secondary nasalization before final **n* (OESecondaryNasalization)

```
define OESecondaryNasalization [  
    {*a} -> {*ǣ} || _ {*n} .#.  
];
```

The broad *-an/-en* split fixes the lower boundary of final **a* nasalization before *n*. Before SC047 OEHeavySyllableNasalApocope, PGmc **bákaną* ‘bake’ yields *†bacen* rather than expected OE *bacan* ‘bake’, and PGmc **bīdaną* ‘bind’ yields *†binden* rather than expected *bindan* ‘bind’. The upper boundary comes from back mutation. After SC059 OEBackMutation, PGmc **stélaną* ‘steal’ yields *†steolan* rather than expected OE *stelan* ‘steal’, and PGmc **wébaną* ‘weave’ yields *†weofan* rather than expected *wefan* ‘weave’. Reciprocal nasal-tail failures place secondary nasalization after apocope, and the later mutation witnesses place it before back mutation; SC046 OEARestoration retains the clearest independent historical support.

47 B allophony

47.1 Historical discussion

The positional alternation of Germanic **b* is a Proto-Germanic distributional feature. Hogg states the Old English distribution clearly: /b/ is a stop initially, after nasals, and in gemination, while the same segment is otherwise realized as a voiced bilabial fricative (Hogg 1992b, 108). Ringe and Taylor support the broader West Germanic background by treating Proto-West-Germanic **b* as a segment whose stop and fricative values depend on position (Ringe and Taylor 2014, 121), and Luick's spelling evidence shows the same labial fricative pattern in Old English (Luick 1914-1940, 107).

The distribution is narrow, but later changes presuppose the stop-fricative alternation. CAPR implements the rule at a late cascade position for computational reasons: the alternation must interact with consonant environments shaped by intermediate rule applications. Its historical stage is Proto-Germanic.

47.2 SC049. Distribution of **b* after vowels and liquids (PGmcBAllophony)

```
define PGmcBAllophony [  
  {*b} -> {*β} || PGmcStarVocalic _,  
  {*b} -> {*β} || [{*l} | {*r}] _  
] .o. [  
  {*β} -> {*b} || _ {*b}  
];
```

The handbooks describe **b*/**bb* as a positional alternation within the consonant system, and one compound supplies its chronological consequence. Before SC037 OECompoundLinkingSyncope, *reġnboga* ‘rainbow’ develops as *†reġnfoga* rather than expected OE *reġnboga*; later placement creates no comparable failure. The witness places b-allophony after compound-linking syncope without turning the alternation into an independent sound law.

48 Sievers-law syncope

48.1 Historical discussion

Sievers' Law concerns a prosodic and morphological adjustment in heavy stems. It is a distributional rule distinct from b-allophony (SC049 PGmcBALlophony). Adamczyk treats the Old English reflexes of the law as historical evidence from weak verbs and related formations (Adamczyk 2001, 61–72). Fulk gives the compact comparative summary through familiar forms such as *bid-dan* 'ask', *sellan* 'give', and *nerian* 'save' (Fulk 2018, 127, §6.15).

Sievers-law syncope is narrow in scope, but its relation to the following palatalization is lexically secure. Its earlier limit is less sharply defined than that of the preceding allophony rule.

48.2 SC050. Sievers-law syncope (SieversLawSyncope)

```
define SieversLawSyncope [  
  {*i} -> 0 || [EnglishStarConsonant | EnglishPalatalConsonant] _ {*j}  
];
```

The Sievers-law reduction **-CijV-** > **-CjV-**, including loss of **i* before **j*, must precede palatalization. If SC050 SieversLawSyncope follows SC052 OEVelarPalatalization, PGmc **strákkijaną* 'stretch' yields [†]*streccan* rather than expected OE *streccan* 'stretch'; earlier placement creates no comparably precise error. The single cluster witness therefore places syncope before velar palatalization.

49 Palatalization of **sk* to **sc*

49.1 Historical discussion

The palatalization of **sk* to Old English **sc* is one of the recognizable early cluster changes in the larger palatalization zone. Campbell distinguishes the cluster from plain velars when he remarks that **sk* is especially prone to palatalization and assibilation (Campbell 1959, 278, §440). Hogg gives the same change a clearer structural place by treating **sk* beside the palatalization of plain velars and before the later West Saxon diphthongal developments (Hogg 1992b, 106–8, 113). Ringe and Taylor make the same sequence explicit when they distinguish the earlier palatalization of velars and **sk* from the later diphthongization after already palatal consonants (Ringe and Taylor 2014, 213–16, §§6.4.1, 6.5.1).

Luick places the cluster change within a broader early movement toward palatal articulation, while still allowing later vowel consequences to form a different chapter of the history (Luick 1914–1940, 157, §168). Fulk’s summary is the most concise warning against overextension: Old English **sc* is palatal except in the well-known back-vowel environments that preserve harder outcomes (Fulk 2018, 28). The result is a historically clear rule, but not an identity between the cluster change and the later umlautal developments.

49.2 SC051. Palatalization of **sk* to **sc* (OESkPalatalization)

```
define OESkPalatalization [
  {*s} {*k} -> {*ʃ} || .#. _
] .o. [
  {*s} {*k} -> {*ʃ} || EnglishStarFrontVowel _ (EnglishStarConsonant | .#.)
] .o. [
  {*s} {*k} -> {*ʃ} || (EnglishStarConsonant | .#.) _ EnglishStarFrontVowel
] .o. [
  {*s} {*k} -> {*ʃ} || _ {*j}
] .o. [
  {*s} {*k} -> {*ʃ} || {*j} _
];
```

The non-fronted vowels of *flasce* ‘flask’ and *wascan* ‘wash’ fix the lower boundary of **sk* > **sc*. Before SC046 OEAREstoration, the forms are fronted too soon, yielding *flæsce* ‘flask’ and *wæscan* ‘wash’ rather than expected OE *flasce* and *wascan*. This places SC051 OESkPalatalization after restoration.

Five witnesses establish the upper boundary collectively. The palatal cluster must already underlie *sceaft* ‘shaft’, *scēar* ‘shear’, *scēap* ‘sheath’, *scēap* ‘sheep’, and *sciold* ‘shield’ before SC056 OEWSPalatalDiphthongization. The **scea-* ‘sea’/**scie-* set therefore places cluster palatalization before the West Saxon vowel change. The cluster change occupies the same palatalization zone as SC052 OEVelarPalatalization while remaining distinct from plain-velar palatalization and the later vowel changes.

50 Velar palatalization before front vowels

50.1 Historical discussion

Luick places the change inside a broad early palatalizing movement. Under the heading “Frühe Verschiebungen in palataler Richtung,” he treats English *k* and *g* before bright vowels together with the larger field of palatal effects (Luick 1914–1940, 157, §168). His emphasis falls on the environment first: velars before bright vowels and in the vicinity of the palatal glide belong to one early phonological sequence. The examples associated with that sequence, such as *ceaster* ‘town’, *geaf* ‘gave’, *giefan* ‘give’, and *giest* ‘guest’, already show that consonantal palatalization and later vowel effects stand close together historically, even when they must be distinguished analytically (Luick 1914–1940, 157–67, §§168–182).

Campbell narrows the picture by distinguishing plain velars from the especially palatal-prone *sk* cluster. His remark that “[*sk*] is more prone to palatalization and assibilation than [*k*]” is brief, but it makes clear that different members of the larger palatal field need not behave identically (Campbell 1959, 278, §440). Elsewhere in the same part of the grammar he uses forms such as *cild* ‘child’, *dæg* ‘day’, *giefan* ‘give’, and *giest* ‘guest’, which show how palatalized velars, palatal influence, and later umlautal outcomes meet in the same region of the lexicon without collapsing into one process (Campbell 1959, 69–72, 89, §§170, 190–191).

Hogg makes the conditioning sharper still. He states that the change takes place when the velar consonant is adjacent to and in the same syllable as a front vowel or the palatal consonant *j* (Hogg 1992b, 106). This formulation replaces a broad list of palatal outcomes with a phonological environment defined by adjacency and syllable structure.

Ringe and Taylor make the chronological relation still clearer. When they write that “after initial velars and **sk* had been palatalized” West-Saxon diphthongization follows, plain velar palatalization becomes an earlier consonantal stage presupposed by later vowel developments (Ringe and Taylor 2014, 215, §6.5.1). Their own examples of the plain-velar rule, such as *weccan* ‘wake’, *licgan* ‘lie’, *lecgan* ‘lay’, *secg* ‘retainer’, *ecg* ‘edge’, *wicg* ‘horse’, and *brycg* ‘bridge’, illustrate the same point in lexical detail: front vowels and *j* create the palatal environment in which plain *k* and *g* cease to behave as plain velars (Ringe and Taylor 2014, 213–14, §6.4.1).

Luick describes a broad early movement; Campbell distinguishes plain velars from the *sk* complex; Hogg specifies the adjacency and syllable conditions; and Ringe and Taylor order the plain-velar change before West-Saxon diphthongization. Plain-velar palatalization thus forms part of a wider palatalizing environment without being identical to its neighboring changes.

50.2 SC052. Palatalization of **k* before front vowels and **j* (OEVelarPalatalizationKFront)

```
define OEVelarPalatalizationKFront [
  {*k} -> {*tʃ} || .#. _ EnglishStarFrontVowel,
  {*k} -> {*tʃ} || _ [{*i} | {*ī}],
  {*k} -> {*tʃ} || _ {*í},
  {*k} -> {*tʃ} || [{*i} | {*ī}] _ EnglishStarFrontVowel,
  {*k} -> {*tʃ} || {*í} _ EnglishStarFrontVowel,
  {*k} -> {*tʃ} || [{*i} | {*ī}] _ .#. ,
  {*k} -> {*tʃ} || {*í} _ .#.
] .o. [
  {*k} {*k} -> {*tʃ} {*tʃ} || _ {*j}
] .o. [
  {*k} -> {*tʃ} || _ {*j}
] ;
```

The *weccan* ‘wake’, *licgan* ‘lie’, and *lecgan* ‘lay’ set identifies front vowels and *j* as the environment for palatalization of *k* (Ringe and Taylor 2014, 213–14, §6.4.1). These forms establish the conditioning; different witnesses establish the chronology.

Applied before Sievers-law syncope, PGmc **strákkijanq* ‘stretch’ yields [†]*strecċan* rather than expected OE *streċċan* ‘stretch’. Applied after i-umlaut fronting, PGmc **kūi* ‘cow’ and **lúnganjō* ‘lungs’ yield *ċy* ‘cows’ and *lunġen* ‘lungs’ rather than expected OE *cý* ‘cows’ and *lungen* ‘lungs’. The front-vowel k change therefore follows Sievers-law syncope and precedes i-umlaut fronting.

50.3 SC052. Velar palatalization before front vowels (OEVelarPalatalization)

```
define OEVelarPalatalization [
  OEVelarPalatalizationKFront
] .o. [
  { *g } -> { *ǥ } || _ EnglishStarFrontVowel,
  { *g } -> { *ǥ } || EnglishStarFrontVowel _ .#.,
  { *g } -> { *ǥ } || EnglishStarFrontVowel _ EnglishStarFrontVowel,
  { *g } -> { *ǥ } || EnglishStarFrontVowel _ [EnglishStarConsonant - { *j }],
  { *g } { *g } -> { *ǥ } { *ǥ } || _ { *j }
] .o. [
  { *g } -> { *ǥ } || _ { *j }
];
```

Plain k and g palatalization in front-vocalic and j-adjacent environments follows sk-palatalization and occupies a sharply defined pre-umlaut interval. Applied before Sievers-law syncope, PGmc **strákkijanq* ‘stretch’ yields [†]*strecċan* rather than expected OE *streċċan* ‘stretch’. Applied after general i-umlaut, PGmc **kūi* ‘cow’ yields [†]*ċy* rather than expected *cý* ‘cows’, and PGmc **lúnganjō* ‘lungs’ yields [†]*lunġen* rather than expected *lungen* ‘lungs’. These witnesses place velar palatalization after Sievers-law syncope and before umlaut.

Luick, Campbell, and Ringe and Taylor place *cild* ‘child’ and *dæg* ‘day’ in a consonantal palatalization that precedes later vowel fronting (Luick 1914–1940, 157, §168; Campbell 1959, 278, §440; Ringe and Taylor 2014, 203–15, §§6.4.1, 6.5.1). The umlautal developments therefore receive plain k and g already reshaped beside front vowels and j.

The sk change belongs to the same palatalizing region with a separate scope. The *streċċan* ‘stretch’ evidence establishes a specific dependency on earlier syncope; it does not merge the two changes into one process.

51 Post-velar **w*-loss and loss of **w* before final **i*

51.1 Historical discussion

The first rule is a narrow loss of **w* after velars in the **ngw* sequence. Ringe and Taylor derive PGmc **singwan* ‘sing’ to Old English *singan* ‘sing’ (Ringe and Taylor 2014, 214, §6.4.2). This comparative evidence establishes the change, although no lexical evidence fixes its order relative to a neighboring rule.

The second rule is historically more legible. Campbell notes the recurring loss of **w* before **i* in unstressed position (Campbell 1959, 167, §406). Ringe and Taylor trace the development of *sǣ* ‘sea’ from earlier **saiwi-* / **sawi-* (Ringe and Taylor 2014, 257, §6.7.1), and Luick gives the same trajectory in his own historical grammar (Luick 1914–1940, 173, §187). The first rule is restricted to the **ngw* sequence; the second has a specific lexical witness and defined earlier and later limits.

51.2 SC053. Loss of **w* after velars (OEPPostVelarWLoss)

```
define OEPPostVelarWLoss [  
    { *w } -> 0 || { *n } { *g } _  
];
```

The comparative development **singwan* > *singan* establishes narrow post-velar **w*-loss in the **ngw* sequence, yielding *singan* ‘sing’. Moving SC053 OEPPostVelarWLoss earlier or later leaves every output unchanged. Its pre-umlaut position therefore rests on comparative evidence, while the present lexicon supplies no neighboring boundary.

51.3 SC054. Loss of **w* before final **i* (OEWLossBeforeI)

```
define OEWLossBeforeI [  
    { *w } -> 0 || EnglishStarVocalic _ { *i } .#.  
];
```

The history of *sǣ* ‘sea’ explains why non-initial **w* disappeared before final unstressed **i*. Campbell describes the loss, Ringe and Taylor derive the form from **saiwi-*/**sawi-*, and Luick gives the parallel trajectory (Campbell 1959, 167, §406; Ringe and Taylor 2014, 257, §6.7.1; Luick 1914–1940, 173, §187). Loss of the glide allowed the preceding vowel to undergo the later fronting and lengthening.

The same witness supplies two distant limits. Before SC020 EAFFinalZDeletion or after SC063 OE-HighVowelApocope, SC054 OEWLossBeforeI yields *†sǣw* rather than expected OE *sǣ* ‘sea’. The loss must therefore follow final z-deletion and precede high-vowel apocope, while its exact position within that broad interval remains source-based.

52 The Old English i-umlaut and West Saxon palatal diphthongization

52.1 Historical discussion

Luick gives the change its traditional scale:

Der wichtigste Fall von palataler Beeinflussung ... war die Veränderung der urenglischen Vokale durch i oder j der Folgesilbe.

(Luick 1914–1940, 166–67, §182)

Campbell gives the most compact classical formulation in English when he writes that “the process known as i-umlaut or i-mutation operates on practically all the sounds which it could theoretically affect in OE” (Campbell 1959, 69, §190). He immediately defines the core conditioning environment as a following i or j, and he goes on to trace the consequences across much of the vowel system, including forms such as *giest* ‘guest’, *giefan* ‘give’, *hierde* ‘shepherd’, and *ieldra* ‘older’ (Campbell 1959, 69–72, §§190–197).

Hogg continues in the same vein: “we come now to a change which is almost as uncontroversial as it is important” (Hogg 1992b, 113). His examples, such as *bryd* ‘bride’, *trymman* ‘strengthen’, *bedd* ‘bed’, *ciest* ‘chest’, and *wiersa* ‘worse’, likewise emphasize that the change is a broad redistribution of vowel quality across the Old English vowel system (Hogg 1992b, 113–14).

The narrower palatal-diphthongal material is described differently. Ringe and Taylor treat West-Saxon diphthongization after initial palatals as a distinct process (Ringe and Taylor 2014, 215, §6.5.1), and Fulk is even more explicit about its chronological delicacy when he calls it “diphthongization by initial palatal consonants (which precedes front umlaut but not breaking)” (Fulk 2018, 74, §4.13). Ringe and Taylor’s examples such as *gielðan* ‘pay’, *sciold* ‘shield’, and *scieppan* ‘create’ show that this narrower process is triggered by already palatal consonants and leads to specifically West-Saxon diphthongal outputs (Ringe and Taylor 2014, 215–16, §6.5.1).

Luick, Campbell, and Hogg treat i-umlaut as a system-wide change. Ringe and Taylor and Fulk distinguish from it a narrower West-Saxon process affecting words after initial palatals. The two changes act in different environments and produce different lexical consequences.

Two further distinctions are essential to their relative chronology. First, the raising of inherited Germanic **e* to **i* before a following high front vocoid is much earlier than Old English i-umlaut. Ringe reconstructs PGmc **giftiz* ‘gift’, with OE plural *gifta* ‘wedding’, and discusses that earlier raising separately (Ringe 2017, 135, pp. 151–153). Ringe and Taylor likewise caution that raising of inherited **e* occurred hundreds of years before the Old English changes; a later repetition is rare and doubtful (Ringe and Taylor 2014, 220). The selected gift input now has the earlier-raised vowel. Its lack of ordinary diphthongization therefore does not date the general West Saxon process. Published e-reconstructions remain genuine alternatives (Orel 2003, 130; Kluge 2011, 359); the lexical discussion compares their evidence and explains the attributed working choice.

Second, the ordinary diphthongization of inherited/fronted non-high vowels must be distinguished from the later treatment of some mutation products after *sc̥*. Campbell separates that small group from his general front-vowel diphthongization: the group includes *scēap* ‘sheath’ beside *scæp* ‘sheath’ (Campbell 1959, 68–69, §§184–185). Ringe and Taylor explicitly place the treatment of the ai-derived mutation product after mutation, giving the same two sheath outcomes (Ringe and Taylor 2014, 235). Their ordinary West Saxon derivations, including *giest* ‘guest’ and *cytel* ‘kettle’, instead pass through palatal diphthongization before mutation (Ringe and Taylor 2014, 215–17, 222).

The historically preferred working account therefore has ordinary palatal diphthongization before Old English mutation, with the separately evidenced later *sc̥* treatment after it. The adopted cascade separates these operations: ordinary diphthongization precedes mutation, and the unchanged late approximation follows it. The sources’ alternate spellings do not by themselves supply an exceptionless conditioning law for the later group; its full conditioner remains unresolved.

52.2 SC056. West Saxon palatal diphthongization (OEWSPalatalDiphthongization)

```
define OEWSPalatalDiphthongization [
  {*æ} -> {*ea} || .#. [{*tʃ} | {*ɰ} | {*ʃ} | {*j}] _ [EnglishStarConsonant |
    ↪ EnglishPalatalConsonant | .#.],
  {*ǣ} -> {*ēa} || .#. [{*tʃ} | {*ɰ} | {*ʃ} | {*j}] _ [EnglishStarConsonant |
    ↪ EnglishPalatalConsonant | .#.],
  {*e} -> {*ie} || .#. [{*tʃ} | {*ɰ} | {*ʃ} | {*j}] _ [EnglishStarConsonant |
    ↪ EnglishPalatalConsonant | .#.],
  {*ē} -> {*īe} || .#. [{*tʃ} | {*ɰ} | {*ʃ} | {*j}] _ [EnglishStarConsonant |
    ↪ EnglishPalatalConsonant | .#.],
  {*é} -> {*īe} || .#. [{*tʃ} | {*ɰ} | {*ʃ} | {*j}] _ [EnglishStarConsonant |
    ↪ EnglishPalatalConsonant | .#.],
  {*ē} -> {*īe} || .#. [{*tʃ} | {*ɰ} | {*ʃ} | {*j}] _ [EnglishStarConsonant |
    ↪ EnglishPalatalConsonant | .#.],
  {*é} -> {*īe} || .#. [{*tʃ} | {*ɰ} | {*ʃ} | {*j}] _ [EnglishStarConsonant |
    ↪ EnglishPalatalConsonant | .#.],
  {*é} -> {*īe} || .#. [{*tʃ} | {*ɰ} | {*ʃ} | {*j}] _ [EnglishStarConsonant |
    ↪ EnglishPalatalConsonant | .#.],
];
```

West Saxon *giēdan* ‘pay’, *sciēd* ‘shield’, and *scieppan* ‘create’ show diphthongization after an already palatal consonant (Ringe and Taylor 2014, 215–16, §6.5.1). Their dialectal and phonological restriction separates this development from system-wide i-umlaut.

Hogg’s *giefan* ‘give’ and *sceap* ‘sheep’ belong to the same palatal-consonant environment (Hogg 1992b, 112). Fulk likewise assigns this diphthongization a place before front mutation and distinguishes the two processes (Fulk 2018, 74, §4.13).

The ordinary live applications comprise *giefan* ‘give’, *giest* ‘guest’, *sceaft* ‘shaft’, *scieran* ‘shear’, *scēap* ‘sheep’, *sciēd* ‘shield’ and *gēar* ‘year’. Gift is unchanged at this rule because its selected vowel already reflects earlier raising. Sheath changes from the mutation product **ǣ* to **ēa*; it supplies evidence for the later *sc* layer, not the date of the ordinary treatment represented by the other examples.

The adopted ordinary process precedes mutation and preserves the split- diphthong and high- i negative controls. The reported absence of a later displacement failure supplies no positive historical terminus.

52.3 SC055. Fronting under i-umlaut (OEIUmlautFronting)

```
define OEIUmlautFronting [
  {*a} -> {*æ} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  {*ā} -> {*ǣ} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  {*e} -> {*i} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  {*o} -> {*e} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  {*ō} -> {*ē} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  {*u} -> {*y} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  {*ū} -> {*ȳ} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  {*á} -> {*ǣ} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  {*é} -> {*i} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  {*ó} -> {*e} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  {*ú} -> {*y} || _ EnglishIUmlautIntervening EnglishIUmlautTrigger
];
```

The breadth of i-umlaut appears in lexical classes that share only a following high front vocoid. The forms *fylgan* ‘follow’, *gylden* ‘golden’, *wyrm* ‘worm’, and *giest* ‘guest’ exemplify the same i- or j- conditioned fronting across different vowels (Ringe and Taylor 2014, 222, §6.6.1; Campbell 1959, 69–72, §§190–191).

The selected cow and lung inputs are negative controls on the present palatalization rule. Moving the composite umlaut rule before that rule yields [†]*cȳ* and [†]*lungēn* instead of *cȳ* ‘cow’ and *lungen* ‘lung’. This constrains the current rule’s productive domain; it does not assign every consonantal

layer the same date. In particular the selected *cȳ* is a dative-singular input, not evidence from an assumed generic plural.

The stored gift and sheath displacement failures constrain the current serialization, not a universal historical upper boundary. The former gift input left an earlier raising to this late rule; sheath represents the later *sc̥* treatment of a mutation product. Moving the entire palatal-diphthongization bundle earlier strands sheath and diphthongizes the model's still-unraised gift vowel. Neither failure overturns the independently supported ordinary palatal-diphthongization-before-mutation account.

52.4 SC055. Raising under i-umlaut (OEIUmlautRaising)

```
define OEIUmlautRaising [
  { *æ } -> { *e } || _ EnglishIUmlautIntervening EnglishIUmlautTrigger
];
```

Raising of umlauted *æ* to *e* continues the same assimilatory event as fronting and therefore shares the chronology of general i-umlaut.

The four displacement controls concern the composite rule. They are not independent tests of this raising component: for example, the cow vowel changes in the fronting component, not in this **æ*-raising clause. Component chronology must follow the source-supported assimilatory event, with ordinary palatal diphthongization and the later *sc̥* extension kept distinct.

The sources do not describe umlaut as simple fronting alone. Campbell notes that the low front vowel changes again before *m* and *n* in most dialects (Campbell 1959, 69, §190), and Hogg likewise treats short front vowels as part of the same assimilatory system (Hogg 1992b, 113).

52.5 SC055. Diphthongal outcomes under i-umlaut (OEIUmlautDiphthong)

```
define OEIUmlautDiphthong [
  { *ea } -> { *ie } || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  { *ēa } -> { *ie } || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  { *io } -> { *ie } || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  { *īo } -> { *ie } || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  { *eo } -> { *ie } || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  { *ēo } -> { *ie } || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  { *ēa } -> { *ie } || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  { *ēo } -> { *ie } || _ EnglishIUmlautIntervening EnglishIUmlautTrigger,
  { *īo } -> { *ie } || _ EnglishIUmlautIntervening EnglishIUmlautTrigger
];
```

Diphthongal outcomes belong to the same system-wide assimilation as simple-vowel fronting and raising. All three therefore belong to a single historical event.

The relevant examples are the recurring West-Saxon *ie* forms cited in the handbooks, including *giest* ‘guest’, *giefan* ‘give’, and *hierde* ‘shepherd’ in Campbell and *ciest* ‘chest’ in Hogg (Campbell 1959, 69–72, 78–80, §§190–191, 248–251; Hogg 1992b, 113–14). These diphthongal outcomes form a distinct part of the general umlautal development alongside simple fronting.

Those composite displacement controls do not isolate diphthongal mutation: neither the cow input nor the gift input has a diphthong here. In the conventional history, diphthongs produced by ordinary palatal diphthongization can be mutated, as in the source derivation of *giest* ‘guest’ (Ringe and Taylor 2014, 216). The adopted derivation now follows that *ea*-to-*ie* source path. The former simple-vowel route converged on the same final form, showing why final agreement alone could not establish the relative chronology.

52.6 SC055. The composite i-umlaut rule (OEIUmlaut)

```
define OEIUmlaut OEIUmlautFronting
```

```
.o. OEIUmlautRaising
.o. OEIUmlautDiphthong;
```

The literature presents fronting, raising, and diphthongal mutation as effects of one historical development. They consequently occupy a single place in the Old English chronology.

The cow/lung displacement results require the present productive palatalization rule not to consume those mutation-created environments. The historical interpretation still depends on the relevant consonantal layer and inherited versus secondary front-vowel conditions.

There is no single source-supported upper boundary at the entire West Saxon bundle. Ordinary palatal diphthongization precedes mutation in the handbook account; the later *sc* treatment of some mutation products follows it. The former gift input and sheath's later layer explained the old bundled serialization, not a date for every historical palatal process.

52.7 Retained late palatal-diphthongization approximation

```
define OELatePalatalDiphthong [
  { *æ } -> { *ēa } || .#. [ { *tʃ } | { *tʃ } | { *ʃ } | { *j } ] _ [ EnglishStarConsonant |
    ↪ EnglishPalatalConsonant | .#. ]
];
```

This support operation retains exactly the former postmutation long-vowel clause. Its sole current application is *scēap* ‘sheath’. The four initial triggers are an unchanged approximation, not a source-proven complete historical conditioner. Campbell and Ringe–Taylor distinguish the later class (Campbell 1959, 68–69; Ringe and Taylor 2014, 235); the incremental implementation does not claim to have resolved it.

53 J-cluster coalescence

53.1 Historical discussion

Only a small lexical group reveals the coalescence of velars with **j*. Plain-velar and **sk* palatalization must already have run before **gj* and **kj* acquire their later outcomes. Campbell, Ringe and Taylor, and Fulk discuss the palatalized and fronted outcomes in *bīēgan* ‘bend’ and *sēcan* ‘seek’ without assigning this later cluster adjustment the status of a major sound law (Campbell 1959, 89, 107–8, §§170, 248–251; Ringe and Taylor 2014, 213–51, §§6.4.1, 6.5.1, 6.6.1–6.6.4; Fulk 2018, 65, 75, §§4.7, 4.13).

53.2 SC057. Coalescence of velar + **j* clusters (OEJClusterCoalescence)

```
define OEJClusterCoalescence (
  [{*g} {*j} -> {*ǵ}]
  .o. [{*k} {*j} -> {*č}]
);
```

The forms *bīēgan* ‘bend’ and *sēcan* ‘seek’ determine the earlier boundary. If coalescence precedes SC052 OEVelarPalatalization, the developments behind *bīēgan* ‘bend’ and *sēcan* ‘seek’ are lost. Related forms such as *fylġan* ‘follow’, *hečġ* ‘hedge’, and *sengan* ‘sing’ fail in the same broader palatalization zone. PGmc **bāugijanq* ‘bow’ yields *†bēagan* rather than expected OE *bīēgan*, and PGmc **sōkijanq* ‘seek’ yields *†sōcan* rather than expected *sēcan*. This demonstrates that velar palatalization preceded coalescence. Nothing in the present lexicon supplies a terminus ante quem.

54 Back mutation

54.1 Historical discussion

West Saxon *giefan* ‘give’ and *wefan* ‘weave’ stand against non-West-Saxon *geofad* ‘gave’ and *weofan* ‘weave’. Ringe and Taylor use this contrast to define the dialectal profile of back mutation (Ringe and Taylor 2014, 319, §6.9.4). Campbell’s treatment of diphthongization before following back vowels includes *heofon* ‘heaven’ (Campbell 1959, 86, §207), while Hogg draws the instructive comparison with breaking (Hogg 1992b, 113). Fulk accordingly separates back mutation from the earlier umlautal changes (Fulk 2018, 69, §4.8).

54.2 SC059. Back mutation before labials and liquids (OEBackMutation)

```
define OEBackMutation [  
  {*e} -> {*eo} || _ [EnglishStarLabial | EnglishStarLiquid] {*u},  
  {*æ} -> {*ea} || _ [EnglishStarLabial | EnglishStarLiquid]  
    ⇨ EnglishBackMutationTrigger,  
  {*é} -> {*éo} || _ [EnglishStarLabial | EnglishStarLiquid] {*u}  
];
```

Three witness forms bracket the chronology. If back mutation precedes SC048 OESecondaryNasalization, forms such as **gébanq* ‘give’ produce *geofan* ‘give’; the expected form is *giefan* ‘give’. **stélanq* ‘steal’ likewise produces *steolan* ‘steal’; the expected form is *stelan* ‘steal’. At the other edge, delaying back mutation until after SC078 OEWeakTailReduction makes **wébanq* ‘weave’ yield *weofan* ‘weave’; the expected form is *wefan* ‘weave’. Thus back mutation follows secondary nasalization but precedes the weak-tail reductions.

55 West Saxon palatal umlaut

55.1 Historical discussion

The reflexes *miht* ‘might’ and *niht* ‘night’ place West Saxon palatal umlaut after the principal umlautal developments. Campbell and Ringe and Taylor describe the forms themselves; Fulk supplies the broader chronology of palatal-vowel change (Campbell 1959, 107–8, §§248–251; Ringe and Taylor 2014, 215–51, §§6.5.1, 6.6.1–6.6.4; Fulk 2018, 65, 75, §§4.7, 4.13).

55.2 SC060. West Saxon palatal umlaut before **h*-clusters (OEWSPalatalUmlaut)

```
define OEWSPalatalUmlaut [  
  {*eo} -> {*i} || _ OEHCluster .#.,  
  {*io} -> {*i} || _ OEHCluster .#.,  
  {*ie} -> {*i} || _ OEHCluster .#.,  
  {*eo} -> {*i} || _ OEHCluster EnglishStarFrontVowel,  
  {*io} -> {*i} || _ OEHCluster EnglishStarFrontVowel,  
  {*ie} -> {*i} || _ OEHCluster EnglishStarFrontVowel,  
  {*éo} -> {*i} || _ OEHCluster .#.,  
  {*ío} -> {*i} || _ OEHCluster .#.,  
  {*íe} -> {*i} || _ OEHCluster .#.,  
  {*éo} -> {*i} || _ OEHCluster EnglishStarFrontVowel,  
  {*ío} -> {*i} || _ OEHCluster EnglishStarFrontVowel,  
  {*íe} -> {*i} || _ OEHCluster EnglishStarFrontVowel  
];
```

The change to **i* before **h*-clusters can be ordered only on its earlier side. If palatal umlaut precedes SC055 OEIUmlaut, the forms behind *miht* ‘might’ and *niht* ‘night’ remain at the overdeveloped stage [†]*mieht* and [†]*nieht* rather than expected OE *miht* and *niht*. Consequently, i-umlaut precedes palatal umlaut. Reordering the latter against any tested later change leaves both witness forms unchanged.

56 Weak-tail nasal loss

56.1 Historical discussion

The pathway from **dōnq* ‘do’ to *dōn* ‘do’ supplies the sole lexical thread through this reduction. Campbell, Hogg, and Fulk place such weak-tail losses among apocope and related late reductions (Campbell 1959, 144–45, §§345–349; Hogg 1992b, 121; Fulk 2018, 91, §5.6). The witness, however, ties the change to a much older development. Its immediate neighbors remain untested.

56.2 SC061. Reduction of final nasal weak-tail endings (OEWeakTailNasalLoss)

```
define OEWeakTailNasalLoss [  
  {*n} {*q} -> {*n} || _ .#.,  
  {*m} {*q} -> {*m} || _ .#.  
];
```

Final weak-tail **-nq* and **-mq* accordingly yield plain **-n* and **-m*.

Only *dōn* ‘do’ constrains the relative order. Placing this loss before the older n-stem loss makes the derivation record no output instead of expected OE *dōn* ‘do’. The older loss must therefore precede weak-tail nasal loss. Nothing in the current lexicon distinguishes among its possible later positions, and one witness cannot establish a wider historical development.

57 High-vowel apocope

57.1 Historical discussion

Final high vowels must survive long enough to condition umlaut before apocope removes them after heavy syllables and in the relevant trisyllabic patterns. Campbell, Hogg, Ringe and Taylor, and Fulk agree on this Old English development, though they differ over the extent of the surrounding syncope (Campbell 1959, 144–45, §§345–349; Hogg 1992b, 121; Ringe and Taylor 2014, 284–303, §§6.8.1, 6.8.4; Fulk 2018, 91, §5.6).

57.2 SC063. High-vowel apocope after heavy syllables and in trisyllables (OEHighVowelApocope)

```
define OEHighVowelApocope [  
  {*i} -> 0 || EnglishStarLongVowel OEAnyConsonant+ _ .#.,  
  {*u} -> 0 || EnglishStarLongVowel OEAnyConsonant+ _ .#.,  
  {*y} -> 0 || EnglishStarLongVowel OEAnyConsonant+ _ .#.,  
  {*i} -> 0 || EnglishStarLongDiphthong OEAnyConsonant+ _ .#.,  
  {*u} -> 0 || EnglishStarLongDiphthong OEAnyConsonant+ _ .#.,  
  {*y} -> 0 || EnglishStarLongDiphthong OEAnyConsonant+ _ .#.,  
  {*i} -> 0 || EnglishStarShortDiphthong OEAnyConsonant OEAnyConsonant+ _ .#.,  
  {*u} -> 0 || EnglishStarShortDiphthong OEAnyConsonant OEAnyConsonant+ _ .#.,  
  {*y} -> 0 || EnglishStarShortDiphthong OEAnyConsonant OEAnyConsonant+ _ .#.,  
  {*i} -> 0 || EnglishStarShortVowel OEAnyConsonant OEAnyConsonant+ _ .#.,  
  {*u} -> 0 || EnglishStarShortVowel OEAnyConsonant OEAnyConsonant+ _ .#.,  
  {*y} -> 0 || EnglishStarShortVowel OEAnyConsonant OEAnyConsonant+ _ .#.,  
  {*i} -> 0 || EnglishStarLongVowel OEAnyConsonant+ EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*u} -> 0 || EnglishStarLongVowel OEAnyConsonant+ EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*y} -> 0 || EnglishStarLongVowel OEAnyConsonant+ EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*i} -> 0 || EnglishStarLongDiphthong OEAnyConsonant+ EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*u} -> 0 || EnglishStarLongDiphthong OEAnyConsonant+ EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*y} -> 0 || EnglishStarLongDiphthong OEAnyConsonant+ EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*i} -> 0 || EnglishStarShortDiphthong OEAnyConsonant OEAnyConsonant+  
    ↳ EnglishStarShortVowel OEAnyConsonant+ _ .#.,  
  {*u} -> 0 || EnglishStarShortDiphthong OEAnyConsonant OEAnyConsonant+  
    ↳ EnglishStarShortVowel OEAnyConsonant+ _ .#.,  
  {*y} -> 0 || EnglishStarShortDiphthong OEAnyConsonant OEAnyConsonant+  
    ↳ EnglishStarShortVowel OEAnyConsonant+ _ .#.,  
  {*i} -> 0 || EnglishStarShortDiphthong OEAnyConsonant EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*u} -> 0 || EnglishStarShortDiphthong OEAnyConsonant EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*y} -> 0 || EnglishStarShortDiphthong OEAnyConsonant EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*i} -> 0 || EnglishStarShortVowel OEAnyConsonant EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*u} -> 0 || EnglishStarShortVowel OEAnyConsonant EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*y} -> 0 || EnglishStarShortVowel OEAnyConsonant EnglishStarShortVowel  
    ↳ OEAnyConsonant+ _ .#.,  
  {*i} -> 0 || EnglishStarShortVowel OEAnyConsonant OEAnyConsonant+  
    ↳ EnglishStarShortVowel OEAnyConsonant+ _ .#.,  
  {*u} -> 0 || EnglishStarShortVowel OEAnyConsonant OEAnyConsonant+  
    ↳ EnglishStarShortVowel OEAnyConsonant+ _ .#.,  
  {*y} -> 0 || EnglishStarShortVowel OEAnyConsonant OEAnyConsonant+  
    ↳ EnglishStarShortVowel OEAnyConsonant+ _ .#.,
```

```

    {*i} -> 0 || EnglishStarLongVowel _ .#.,
    {*u} -> 0 || {*x} _ .#.,
    {*y} -> 0 || {*x} _ .#.,
    {*i} -> 0 || {*x} _ .#.
];

```

Final **i*, **u*, and **y* cannot disappear before completing their umlautal work. Applied before SC055 OEIUmlaut, PGmc **kūi* ‘cow’ yields [†]*cū* rather than expected OE *cȳ* ‘cow’, and PGmc **brūdiz* ‘bride’ yields [†]*brūd* rather than expected OE *brȳd* ‘bride’. Conversely, if apocope waits until after SC072 OEUnstressedLongVowelShortening, PGmc **fūrxtīnaz* ‘fright’ yields [†]*fyrht* rather than expected OE *fyrhte* ‘fright’. The three witnesses establish the sequence i-umlaut, high-vowel apocope, unstressed long-vowel shortening.

58 Post-apocope **n*-loss and medial syncope

58.1 Historical discussion

Evidence for post-apocope reduction is strikingly uneven. The inherited feminine *in*-stem represented by Gothic *faurhitei*, OE *fyrhtu*, and oblique OE *fyrhte* supplies the relevant evidence (Orel 2003, 120; Ringe and Taylor 2014, 380–81; Campbell 1959, 236, §589.7). No comparable witness orders the medial syncope that follows. Hogg, Ringe and Taylor, and Fulk describe both processes within the late history of weak syllables (Hogg 1992b, 121; Ringe and Taylor 2014, 264–303, §§6.7.3–6.8.4; Fulk 2018, 91, §5.6).

58.2 SC064. Loss of stem-final **n* after long **ī* (NWGmcInStemNLoss)

```
define NWGmcInStemNLoss [{*n} -> 0 || {*ī} _ .#.];
```

Only final **n* after long **ī* is at issue, as in the inherited *in*-stem behind OE *fyrhte* ‘fright’.

CAPR models the oblique OE form through the Proto-Germanic genitive singular **fūrxtīnaz* ‘fright’, following the project convention of using an appropriate non-nominative paradigm cell when the nominative does not supply the required derivation. Within this selected genitive derivation, the same input fixes both ordering boundaries. Before SC041 PWGmcFinalBareALoss, PGmc **fūrxtīnaz* ‘fright’ yields *†fyrhten* rather than expected OE *fyrhte* ‘fright’. After SC072 OEUnstressedLongVowelShortening, PGmc **fūrxtīnaz* again yields *†fyrhten* rather than expected *fyrhte* ‘fright’. I therefore order final bare-a loss, stem-final *n*-loss, and unstressed long-vowel shortening in that sequence. Both boundaries are firm within the selected genitive derivation and depend on one inherited lexeme/paradigm.

58.3 SC065. Medial syncope before dentals after heavy syllables (OEMedialSyncope)

Loss of medial **i* before dentals belongs to the late weak-tail history described by Hogg, Ringe and Taylor, and Fulk (Hogg 1992b, 121; Ringe and Taylor 2014, 264–303, §§6.7.3–6.8.4; Fulk 2018, 91, §5.6).

```
define OEMedialSyncope [  
  {*i} -> 0 || EnglishStarLongVowel OEAnyConsonant+ _ [{*θ}|{*ð}|{*d}|{*t}],  
  {*i} -> 0 || EnglishStarLongDiphthong OEAnyConsonant+ _ [{*θ}|{*ð}|{*d}|{*t}],  
  {*i} -> 0 || EnglishStarShortVowel OEAnyConsonant OEAnyConsonant+ _  
    ↳ [{*θ}|{*ð}|{*d}|{*t}]  
];
```

No diagnostic word establishes a local chronology. Moving medial syncope to either end of the tested range leaves every output unchanged. Its handbook placement after apocope and before later cluster simplification therefore remains preferable, but the present lexicon cannot demonstrate it.

59 Late syncope and degemination

59.1 Historical discussion

Vowel loss creates the clusters upon which later assimilation and degemination operate. Hogg and Ringe and Taylor describe this dependence, while Brunner’s *netle* ‘nettle’ beside later *nete* ‘nettle’ supplies a concrete lexical type (Hogg 1992b, 121; Ringe and Taylor 2014, 264–96, §§6.7.3–6.8.2; Brunner 1965, 144–45, §§158–159). Fulk places this syncope after i-umlaut (Fulk 2018, 91, §5.6).

The three relations are not equally secure. Lexical evidence orders syncope and degemination; the intervening dental assimilation has no independent ordering witness.

59.2 SC066. L-adjacent syncope in medial syllables (OELAdjacentSyncope)

```
define OELAdjacentSyncope [  
  {*i} -> 0 || EnglishStarShortVowel OEAnyConsonant+ _ {*l},  
  {*i} -> 0 || EnglishStarLongVowel OEAnyConsonant+ _ {*l},  
  {*i} -> 0 || EnglishStarDiphthong OEAnyConsonant+ _ {*l}  
];
```

The loss of medial **i* before **l* is late enough to preserve earlier umlaut, as *netle* ‘nettle’ and *spinl* ‘spindle’ demonstrate.

Placed before i-umlaut, PGmc **nátílōn* ‘nettle’ yields [†]*nætle* rather than expected OE *netle* ‘nettle’, and PGmc **spénnilō* ‘spindle’ yields [†]*spenl* rather than expected *spinl* ‘spindle’. Placed after preconsonantal degemination, PGmc **spénnilō* yields [†]*spinnl* rather than expected *spinl*. The witnesses therefore establish the sequence i-umlaut, l-adjacent syncope, preconsonantal degemination. The first relation separates two historical phases; the second is a direct feeding relation, since syncope creates the cluster that degemination simplifies.

59.3 SC067. Dental assimilation in newly formed clusters (OEDentalAssimilation)

```
define OEDentalAssimilation [  
  {*θ} -> 0 || {*t} _  
];
```

Loss of **θ* after **t* resolves a dental cluster produced by syncope (Hogg 1992b, 121; Ringe and Taylor 2014, 279–96, §§6.7.5, 6.8.2). No witness distinguishes its position: moving dental assimilation across every tested neighbor leaves the outputs unchanged. I nevertheless place it after syncope, which supplies its input, and before the more general cluster simplification described in the handbooks. This order is phonologically motivated, not established by a lexical contrast.

59.4 SC068. Preconsonantal degemination before sonorants (OEPreconsonantalDegemination)

```
define OEPreconsonantalDegemination OEPreconsonantalDegemTT .o.  
  ⇨ OEPreconsonantalDegemNN;
```

Preconsonantal **tt* and **nn* simplify only after syncope has created a following sonorant cluster, as in *spinl* ‘spindle’ (Ringe and Taylor 2014, 279–96, §§6.7.5, 6.8.2).

Placed before l-adjacent syncope, PGmc **spénnilō* ‘spindle’ yields [†]*spinnl* rather than expected OE *spinl* ‘spindle’. Syncope must therefore create the cluster before degemination simplifies it.

Reordering degemination against any tested later change leaves the witness unchanged, so no terminus ante quem is known.

60 Early o-shortening

60.1 Historical discussion

After the principal palatal andumlaut changes, unstressed vowels undergo shortening, fronting, merger, and sometimes complete loss. Campbell describes the early shortening of unaccented long vowels, while Hogg, Ringe and Taylor, and Fulk relate it to apocope, syncope, and the later reductions (Campbell 1959, 148, §355; Hogg 1992b, 121; Ringe and Taylor 2014, 298–314, §§6.8.3–6.9.3; Fulk 2018, 90–96, §§5.6–5.7).

Early o-shortening has only a distant earlier boundary. The rules that follow, especially SC070 OEUnstressedFrontingEarly and SC072 OEUnstressedLongVowelShortening, have more closely defined relations.

60.2 SC069. Early shortening of unstressed *ō before nasals (OEEarlyOShortening)

```
define OEEarlyOShortening [  
  { *ō } -> { *a } || EnglishStarVocalic [EnglishStarConsonant |  
    ↪ EnglishPalatalConsonant]+ _ EnglishStarNasal  
];
```

The rule shortens unstressed long *ō before a following nasal. Because this shortening happens early, the resulting *a can still participate in the later fronting and merger that shape many weak final syllables.

Moving the rule before SC023 PNWGmcNStemNLoss, PGmc **nēdrōn* ‘adder’ yields †*nædran* rather than expected OE *nædre* ‘adder’, PGmc **érθōn* ‘earth’ yields †*eorþan* rather than expected *eorþe* ‘earth’, and PGmc **fláskōn* ‘flask’ yields †*flaskan* rather than expected *flasce* ‘flask’. The same earlier shift also disrupts forms such as *heorte* ‘heart’ and *līne* ‘line’. This broad set of failures requires SC069 OEEarlyOShortening to follow SC023 PNWGmcNStemNLoss.

If the rule is moved later within the tested sequence, no output differs from the expected one. The lexical evidence therefore does not identify a corresponding later constraint. The sources place early *ō-shortening before the later weak-tail changes without fixing a closer local order.

61 Early unstressed fronting and later o-shortening

61.1 Historical discussion

Campbell distinguishes the shortening of unaccented long vowels, while Hogg, Ringe and Taylor, and Fulk place fronting and shortening within a later history of syncope and final-vowel adjustment (Campbell 1959, 148, §355; Hogg 1992b, 121; Ringe and Taylor 2014, 298–314, §§6.8.3–6.9.3; Fulk 2018, 90–96, §§5.6–5.7). Earlier unstressed fronting precedes later o-shortening.

SC070 OEUnstressedFrontingEarly has both an earlier and a later lexical breakpoint. SC071 OELateOShortening confirms their reciprocal order, but no lexical evidence fixes its later boundary.

61.2 SC070. Early fronting of unstressed *a (OEUnstressedFrontingEarly)

```
define OEUnstressedFrontingEarly OEUnstressedAFronting;
```

The rule fronts unstressed *a to *æ after the earlier shortening has created a frontable vowel but before the later shortening of unstressed *ō. It produces endings such as OE *-en* in *lungen* ‘lungs’.

If the rule is moved before SC052 OEVelarPalatalization, PGmc **lúnganjō* ‘lungs’ yields *†lungen* rather than expected OE *lungen* ‘lungs’. If the rule is delayed until after SC071 OELateOShortening, PGmc **búrōθi* ‘bears’ yields *†boreþ* rather than expected OE *boraþ* ‘bears’, and PGmc **ménōθz* ‘month’ yields *†mōneþ* rather than expected *mōnaþ* ‘month’. The witness forms require SC070 OEUnstressedFrontingEarly to follow SC052 OEVelarPalatalization and precede SC071 OELateOShortening.

The relation to SC071 OELateOShortening is local. The earlier boundary at SC052 OEVelarPalatalization places fronting after the older palatal developments.

61.3 SC071. Later shortening of unstressed *ō (OELateOShortening)

The following rule handles the later shortening stage.

```
define OELateOShortening [  
  {*ō} -> {*o} || EnglishStarVocalic [EnglishStarConsonant |  
    ↪ EnglishPalatalConsonant]+ _ [EnglishStarConsonant |  
    ↪ EnglishPalatalConsonant]*  
];
```

The rule shortens the remaining unstressed long *ō after fronting. The shortened vowel is then resolved by the following medial/final distribution, not directly as *a* (Stausland Johnsen 2015, 28–31).

Moving the rule before SC070 OEUnstressedFrontingEarly makes PGmc **búrōθi* ‘bears’ yield *†boreþ* rather than expected OE *boraþ* ‘bears’, and PGmc **líznoθi* ‘learns’ yield *†liorneþ* rather than expected *liornaþ* ‘learns’. The contrast requires SC071 OELateOShortening to follow SC070 OEUnstressedFrontingEarly.

61.4 SC099. Medial raising of shortened unstressed *o (OEMedUnstressedORaising)

```
define OEMedUnstressedORaising [  
  {*o} -> {*u} || EnglishStarVocalic [EnglishStarConsonant |  
    ↪ EnglishPalatalConsonant]+ _ [EnglishStarConsonant |  
    ↪ EnglishPalatalConsonant]* EnglishStarVocalic  
];
```

After SC071 OELateOShortening, the shortened vowel gives *u* in an unstressed medial syllable. The rule encodes Stausland Johnsen’s statistically supported account of West Saxon *ō*-verb pasts, not a general rule for inherited short **o* or for nominal morphology (Stausland Johnsen 2015, 28–31, 36). His diagnostic derivation is PGmc **wúndōdē* ‘wounded’ > *†wundode* > OE *wundude* ‘wounded’ (Stausland Johnsen 2015, 28–29).

61.5 SC100. Final lowering of shortened unstressed **o* (OEFinalUnstressedOLowering)

```
define OEFinalUnstressedOLowering [
  {*o} -> {*a} || EnglishStarVocalic [EnglishStarConsonant |
    ↪ EnglishPalatalConsonant]+ _ [EnglishStarConsonant |
    ↪ EnglishPalatalConsonant]* .#.
];
```

In a final syllable the same shortened vowel gives *a*. Thus the existing month control continues PGmc **mēnōθz* ‘month’ through shortened **o* to OE *mōnaþ* ‘month’, while **wúndōdē* ‘wounded’ takes SC099 OEMedUnstressedORaising instead. The medial/final contrast and its chronology after long-vowel shortening are Stausland Johnsen’s analysis (Stausland Johnsen 2015, 28–31).

62 Unstressed long-vowel shortening and ae-merger

62.1 Historical discussion

Campbell describes the shortening of unaccented long vowels, and Ringe and Taylor place it among the last prehistoric Old English changes before the merger of unstressed *æ with *e (Campbell 1959, 148, §355; Hogg 1992b, 121; Ringe and Taylor 2014, 298–314, §§6.8.3–6.9.3; Fulk 2018, 90–96, §§5.6–5.7).

SC072 OEUnstressedLongVowelShortening and SC073 OEUnstressedAEMerger have a reciprocal ordering relation. SC064 NWGmcInStemNLoss supplies the earlier boundary of shortening, and SC085 OEHLoss the later boundary of the merger.

62.2 SC072. Shortening of unstressed long vowels (OEUnstressedLongVowelShortening)

```
define OEUnstressedLongVowelShortening OEUnstressedLongVowelShortening1
  .o. OEUnstressedLongVowelShortening2
  .o. OEUnstressedLongVowelShortening3
  .o. OEUnstressedLongVowelShortening5
  .o. OEUnstressedLongVowelShortening6
  .o. OEUnstressedLongVowelShortening7
  .o. OEUnstressedLongVowelShortening8;
```

The rule shortens the remaining unstressed long vowels before weak final syllables reach their later forms. A small group of lexical witnesses fixes its chronology.

If the rule is moved before SC064 NWGmcInStemNLoss, PGmc *fúrxtīnaz ‘fright’ yields †fyrhten rather than expected OE fyrhte ‘fright’. If the rule is delayed until after SC073 OEUnstressedAEMerger, PGmc *nédrōn ‘adder’ yields †nædræ rather than expected OE nædre ‘adder’, and PGmc *fādēr ‘father’ yields †fædær rather than expected fæder ‘father’. These outputs require SC072 OEUnstressedLongVowelShortening to follow SC064 NWGmcInStemNLoss and precede SC073 OEUnstressedAEMerger.

Shortening therefore follows the earlier weak-tail preparation and immediately precedes the merger.

62.3 SC073. Merger of unstressed *æ with *e (OEUnstressedAEMerger)

The following rule handles the merger stage.

```
define OEUnstressedAEMerger OEWeakTailReduction3;
```

The rule merges unstressed *æ with *e after shortening has produced the weak final vowels, yielding the ordinary OE -e spellings.

Its earlier and later relations are both concrete. If the rule is moved before SC072 OEUnstressedLongVowelShortening, PGmc *nédrōn ‘adder’ yields †nædræ rather than expected OE nædre ‘adder’, and PGmc *fādēr ‘father’ yields †fædær rather than expected fæder ‘father’. If the rule is delayed until after SC085 OEHLoss, PGmc *tāixōn ‘toe’ yields †tāæ rather than expected OE tā ‘toe’. These failures show that SC072 OEUnstressedLongVowelShortening must come before SC073 OEUnstressedAEMerger, and that SC073 OEUnstressedAEMerger must come before SC085 OEHLoss.

The lexical evidence fixes the local order after SC072 OEUnstressedLongVowelShortening and places the merger before the later h-loss and contraction.

63 Medial unstressed-i lowering

63.1 Historical discussion

Hogg and Ringe and Taylor treat the late weakening and merger of unstressed vowels as a continuing history (Hogg 1992b, 121; Ringe and Taylor 2014, 327–32, §§6.9.5–6.9.6). SC074 OMedUnstressedILowering1 lowers medial unstressed *i*; SC075 OMedUnstressedILowering preserves *i* before **ng* in words of the *scilling* ‘shilling’ type.

General lowering precedes the restricted restoration before **ng*. The evidence is narrower than that for SC072 OEUnstressedLongVowelShortening and SC073 OEUnstressedAEMerger.

63.2 SC074. First medial unstressed-i lowering (OMedUnstressedILowering1)

```
define OMedUnstressedILowering1 [  
  {*i} -> {*e} || EnglishStarVocalic [EnglishStarConsonant |  
    ↪ EnglishPalatalConsonant]+ _  
];
```

The rule lowers medial unstressed **i* to **e* after a preceding vocalic syllable. The resulting *e*-outcome is reversed before **ng*.

If the rule is moved before SC072 OEUnstressedLongVowelShortening, PGmc **fúrxtīnaz* ‘fright’ yields *†fyrhti* rather than expected OE *fyrhte* ‘fright’. If it is delayed until after SC075 OMedUnstressedILowering, PGmc **skillingaz* ‘shilling’ yields *†scilleng* rather than expected *scilling* ‘shilling’. The derivations require SC074 OMedUnstressedILowering1 to follow SC072 OEUnstressedLongVowelShortening and precede SC075 OMedUnstressedILowering.

The evidence is narrow on each side. The rule follows unstressed long-vowel shortening and precedes the more specific **ng* preservation.

63.3 SC075. Preservation of medial unstressed **i* before **ng* (OMedUnstressedILowering)

The following rule reverses the lowering before **ng*.

```
define OMedUnstressedILowering [  
  {*e} -> {*i} || _ {*n} {*g}  
];
```

The rule restores **i* before **ng*, preventing the broader lowering from producing the wrong medial vowel in forms such as *scilling* ‘shilling’.

Moving the rule before SC074 OMedUnstressedILowering1 makes PGmc **skillingaz* ‘shilling’ yield *†scilleng* rather than expected OE *scilling* ‘shilling’. On this evidence, I take SC075 OMedUnstressedILowering to follow SC074 OMedUnstressedILowering1. Moving it later within the tested range creates no equally sharp failure.

64 Prefix i-reduction

64.1 Historical discussion

Late weak-tail reduction affects unstressed prefixes as well as inflectional endings and medial vowels. Fulk’s discussion of prefix vowels accounts for OE **be-* and **ne-* (Fulk 2018, 97, §5.7). Hogg and Ringe and Taylor place such weakening within the broader late history of unstressed vowels (Hogg 1992b, 121; Ringe and Taylor 2014, 298–332, §§6.8.3–6.9.6).

The tested forms do not determine the rule’s position relative to a neighboring change.

64.2 SC076. Reduction of prefixal **i* in unstressed position (OEPrefixIReduction)

```
define OEPrefixIReduction [  
  {*i} -> {*ë} || .#. [{*b} | {*n}] _ [EnglishStarConsonant |  
    ↳ EnglishPalatalConsonant] EnglishStarVocalic  
];
```

The rule reduces unstressed prefixal **i* to a weaker vowel in the *bi-* and *ni-* type prefixes before a consonant plus a following vowel. The development accounts for later prefix spellings such as OE **be-* and **ne-*.

If the rule is moved earlier or later within the tested sequence, no output differs from the expected one. The lexical evidence therefore does not place SC076 OEPrefixIReduction before or after any specific neighboring change.

The handbooks attest late prefix-vowel weakening, but the precise placement remains approximate. No lexical failure fixes it.

65 Weak-tail reduction

65.1 Historical discussion

Campbell, Hogg, Ringe and Taylor, and Fulk describe a late history in which apocope, shortening, contraction, and further weak-tail reductions reshape final syllables (Campbell 1959, 148, §355; Hogg 1992b, 121; Ringe and Taylor 2014, 298–314, §§6.8.3–6.9.3; Fulk 2018, 90–91, §5.6). Lexical failures place the remaining weak-tail reduction after unstressed fronting and before contraction.

65.2 SC078. Reduction of remaining weak-tail vowels (OEWeakTailReduction)

```
define OEWeakTailReduction OEWeakTailReduction1;
```

The rule reduces the remaining weak-tail vowels, preventing a broad class of *-en* and extra-vowel outcomes.

I place the change after SC070 OEUnstressedFrontingEarly and before SC086 OEContraction. Moving it before SC070 OEUnstressedFrontingEarly, PGmc **bákanq* ‘bake’ yields [†]*bacen* rather than expected OE *bacan* ‘bake’, and PGmc **bíndanq* ‘bind’ yields [†]*binden* rather than expected *bindan* ‘bind’, alongside a much wider set of comparable *-en* failures. If the rule is delayed until after SC086 OEContraction, PGmc **fléuxanq* ‘flee’ yields [†]*flēoan* rather than expected OE *flēon* ‘flee’, and PGmc **sláxanq* ‘slay’ yields [†]*sleaan* rather than expected *slēan* ‘slay’.

The earlier boundary spans a wide interval and does not establish a close neighboring relation. The later boundary is narrower: SC078 OEWeakTailReduction precedes SC086 OEContraction.

66 Final-j loss and final geminate simplification

66.1 Historical discussion

After SC079 OEJLossAfterHeavy removes **j* in heavy environments, forms such as *lungen* ‘lungs’ acquire a final geminate. SC080 OEFinalGeminateSimplification then removes the second nasal.

SC079 OEJLossAfterHeavy has a broad earlier boundary at SC055 OEIUmlaut. SC080 OEFinalGeminateSimplification is fixed only by the final *nn* outcome in the following derivation.

66.2 SC079. Loss of **j* after heavy syllables (OEJLossAfterHeavy)

```
define OEJLossAfterHeavy [  
  {*j} -> 0 || (EnglishStarLongVowel | EnglishStarDiphthong)  
  ↳ [EnglishStarConsonantNoR | EnglishPalatalConsonant] _ ,  
  {*j} -> 0 || EnglishStarShortVowel [EnglishStarConsonant |  
  ↳ EnglishPalatalConsonant] [EnglishStarConsonantNoR |  
  ↳ EnglishPalatalConsonant] _  
];
```

The rule removes **j* after the relevant heavy-syllable configurations, after the earlier umlaut-sensitive vocalism has developed. The affected glide is **j*.

If the rule is moved before SC055 OEIUmlaut, PGmc **galáubijanq* ‘believe’ yields *†gelēafan* rather than expected OE *geliefan* ‘believe’, PGmc **báugijanq* ‘bow’ yields *†bēagan* rather than expected *bīegan* ‘bow’, and PGmc **fúlгийнq* ‘follow’ yields *†fulgan* rather than expected *fylgan* ‘follow’. If it is delayed until after SC080 OEFinalGeminateSimplification, PGmc **lúnganjō* ‘lungs’ yields *†lungenn* rather than expected OE *lungen* ‘lungs’. I accordingly take SC079 OEJLossAfterHeavy to follow SC055 OEIUmlaut and precede SC080 OEFinalGeminateSimplification.

The earlier boundary is broad, but the relation to final geminate simplification is local.

66.3 SC080. Simplification of final geminates (OEFinalGeminateSimplification)

The following rule handles the final simplification directly.

```
define OEFinalGeminateSimplification [  
  {*n} -> 0 || {*n} _ .#.  
];
```

The rule removes the extra final nasal in forms where the preceding derivation has already created a final geminate.

Moving the rule before SC079 OEJLossAfterHeavy makes PGmc **lúnganjō* ‘lungs’ yield *†lungenn* rather than expected OE *lungen* ‘lungs’. These failures require SC080 OEFinalGeminateSimplification to follow SC079 OEJLossAfterHeavy. Moving it later within the tested range before SC087 OERMetathesis creates no new failure.

67 J-strengthening, vocalization, and ei-contraction

67.1 Historical discussion

SC081 OEJStrengtheningAfterFrontDiphthong preserves a consonantal outcome after front diphthongs. SC082 OEIntervocalicJVocalization then vocalizes the remaining intervocalic **j*, and SC083 OEUnstressedEIContraction removes the resulting *ei*-like sequence in weak verbal endings.

The output of each rule conditions the next. SC082 OEIntervocalicJVocalization has local lexical evidence on both sides; SC081 OEJStrengtheningAfterFrontDiphthong has a distant earlier boundary, and SC083 OEUnstressedEIContraction has no tested later boundary.

67.2 SC081. Strengthening of **j* after front diphthongs (OEJStrengtheningAfterFrontDiphthong)

```
define OEJStrengtheningAfterFrontDiphthong [  
  {*j} -> {*ʒ} || [{*ēa}|{*éa}|{*īe}|{*īe}|{*éa}] _ EnglishStarVocalic  
];
```

After the relevant front diphthongs, **j* first strengthened to a consonantal outcome; otherwise it would have vocalized too early.

If the rule is moved before SC055 OEIUmlaut, PGmc **stráwjanq* ‘strew’ yields [†]*strēagan* rather than expected OE *strīegan* ‘strew’. If it is delayed until after SC082 OEIntervocalicJVocalization, the same PGmc form yields [†]*strīeian* rather than *strīegan*. The order test requires SC081 OEJStrengtheningAfterFrontDiphthong to follow SC055 OEIUmlaut and precede SC082 OEIntervocalicJVocalization.

The earlier constraint reaches back to SC055 OEIUmlaut and therefore defines a wide interval. The *strīegan* ‘strew’ derivation fixes the local relation to SC082 OEIntervocalicJVocalization.

67.3 SC082. Intervocalic vocalization of **j* (OEIntervocalicJVocalization)

```
define OEIntervocalicJVocalization [  
  {*j} -> {*i} || EnglishStarVocalic _ EnglishStarVocalic  
];
```

The rule vocalizes intervocalic **j* to **i*, creating the *ei*-like sequence later removed by SC083 OEUnstressedEIContraction in many weak verb forms.

Moving the rule before SC081 OEJStrengtheningAfterFrontDiphthong makes PGmc **stráwjanq* ‘strew’ yield [†]*strīeian* rather than expected OE *strīegan* ‘strew’. Delaying it until after SC083 OEUnstressedEIContraction makes PGmc **búrōjanq* ‘bore’ yield [†]*boreian* rather than expected OE *borian* ‘bore’, PGmc **xándlōjanq* ‘handle’ yield [†]*handleian* rather than expected *handlian* ‘handle’, and PGmc **mákōjanq* ‘make’ yield [†]*maceian* rather than expected *macian* ‘make’. The witness forms require SC082 OEIntervocalicJVocalization to follow SC081 OEJStrengtheningAfterFrontDiphthong and precede SC083 OEUnstressedEIContraction.

SC082 OEIntervocalicJVocalization is therefore ordered between strengthening and contraction.

67.4 SC083. Contraction of unstressed *ei* (OEUnstressedEIContraction)

The final rule removes the extra unstressed *e* before *i*.

```
define OEUnstressedEIContraction [  
  {*e} -> ∅ || EnglishStarVocalic [EnglishStarConsonant |  
    ↪ EnglishPalatalConsonant]+ _ {*i}
```

The rule contracts the unstressed *ei*-like sequence that the preceding vocalization would otherwise leave behind in forms such as *borian* ‘bore’ and *liccian* ‘lick’.

Moving the rule before SC082 OEIntervocalicJVocalization makes PGmc **búrōjaną* ‘bore’ yield [†]*boreian* rather than expected OE *borian* ‘bore’, PGmc **líznojaną* ‘learn’ yield [†]*liorneian* rather than expected *liornian* ‘learn’, and PGmc **líkkōjaną* ‘lick’ yield [†]*licceian* rather than expected *liccian* ‘lick’. The contrast requires SC083 OEUnstressedEIContraction to follow SC082 OEIntervocalicJVocalization. Moving it later within the tested range before SC087 OERMetathesis creates no new failure.

68 H-loss and contraction

68.1 Historical discussion

When SC085 OEHLoss removes intervocalic **h*, it creates hiatus. SC086 OEContraction immediately resolves the resulting vowel sequence.

Ringe and Taylor describe this late sequence of *h*-loss and contraction (Ringe and Taylor 2014, 305–14, §§6.9.1–6.9.3). Fulk places the contracted verbs in a broader Germanic context (Fulk 2018, 270, §12.21), and Luick describes the corresponding West Germanic contractions (Luick 1914–1940, 165).

68.2 SC085. Loss of intervocalic **h* (OEHLoss)

```
define OEHLoss [  
  {*x} -> 0 || EnglishStarVocalic _ EnglishStarVocalic  
];
```

The rule removes intervocalic **h*, creating the hiatus that later contraction must resolve.

If the rule is moved before SC073 OEUnstressedAEMerger, PGmc **táixōn* ‘toe’ yields [†]*tāæ* rather than expected OE *tā* ‘toe’. If it is delayed until after SC086 OEContraction, PGmc **fléuxanq* ‘flee’ yields [†]*flēoan* rather than expected OE *flēon* ‘flee’, PGmc **sláxanq* ‘slay’ yields [†]*sleaan* rather than expected *slēan* ‘slay’, PGmc **téxun* ‘draw’ yields [†]*teoon* rather than expected *tēon* ‘draw’, and PGmc **táixōn* yields [†]*tāe* rather than expected *tā*. These outputs require SC085 OEHLoss to follow SC073 OEUnstressedAEMerger and precede SC086 OEContraction.

The earlier boundary rests on one witness; the four later witnesses establish the immediate relation to contraction.

68.3 SC086. Contraction of the resulting hiatus (OEContraction)

The following rule contracts the hiatus left by SC085 OEHLoss.

```
define OEContraction [  
  {*a} {*a} -> {*ā},  
  {*e} {*e} -> {*ē},  
  {*i} {*i} -> {*ī},  
  {*o} {*o} -> {*ō},  
  {*u} {*u} -> {*ū},  
  {*ea} {*a} -> {*ēa},  
  {*ēa} {*a} -> {*ēa},  
  {*eo} {*a} -> {*ēo},  
  {*ēo} {*a} -> {*ēo},  
  {*eo} {*o} -> {*ēo},  
  {*ēo} {*o} -> {*ēo},  
  {*éo} {*o} -> {*éó},  
  {*éó} {*o} -> {*éó},  
  {*ā} {*a} -> {*ā},  
  {*ā} {*e} -> {*ā},  
  {*ē} {*a} -> {*ē},  
  {*ē} {*e} -> {*ē},  
  {*é} {*a} -> {*é},  
  {*é} {*e} -> {*é},  
  {*ī} {*a} -> {*ī},  
  {*ī} {*e} -> {*ī},  
  {*í} {*a} -> {*í},  
  {*í} {*e} -> {*í},  
  {*ō} {*a} -> {*ō},  
  {*ō} {*e} -> {*ō},  
  {*ū} {*a} -> {*ū},
```

{ *ū } { *e } -> { *ū }];

The rule contracts the vowel sequences created after *h*-loss, producing *flēon* ‘flee’, *slēan* ‘slay’, and *tēon* ‘draw’.

Moving contraction before SC085 OEHLoss makes PGmc **fléuxanq* ‘flee’ yield *†flēoan* rather than expected OE *flēon* ‘flee’, PGmc **sláxanq* ‘slay’ yield *†sleaen* rather than expected *slēan* ‘slay’, PGmc **téxun* ‘draw’ yield *†teoon* rather than expected *tēon* ‘draw’, and PGmc **táixōn* ‘toe’ yield *†tāe* rather than expected *tā* ‘toe’. The derivations require SC086 OEContraction to follow SC085 OEHLoss. Moving it later within the tested range before SC087 OERMetathesis creates no new failure. The more distant SC078 OEWeakTailReduction relation establishes only that weak-tail reduction precedes contraction.

69 R-metathesis

69.1 Historical discussion

Sievers-Brunner describes r-metathesis in forms such as *berstan* ‘burst’, *forst* ‘frost’, and *cærse* ‘cress’ (Brunner 1965, 159, §179). Luick likewise treats it as a later rearrangement whose interaction with breaking remains variable (Luick 1914–1940, 201).

The evidence establishes that breaking precedes metathesis. It does not establish an ordering relation between SC086 OEContraction and SC087 OERMetathesis.

69.2 SC087. Metathesis of **r* with a following short vowel (OERMetathesis)

```
define OERMetathesis [  
  {*r} {*e} -> {*e} {*r} || EnglishStarConsonant _ {*s} {*t},  
  {*r} {*u} -> {*u} {*r} || EnglishStarConsonant _ {*s} {*t},  
  {*r} {*i} -> {*i} {*r} || EnglishStarConsonant _ {*s} {*t},  
  {*r} {*o} -> {*o} {*r} || EnglishStarConsonant _ {*s} {*t},  
  {*r} {*a} -> {*a} {*r} || EnglishStarConsonant _ {*s} {*t},  
  {*r} {*é} -> {*é} {*r} || EnglishStarConsonant _ {*s} {*t},  
  {*r} {*ó} -> {*ó} {*r} || EnglishStarConsonant _ {*s} {*t},  
  {*r} {*á} -> {*á} {*r} || EnglishStarConsonant _ {*s} {*t}  
];
```

The rule moves **r* across a following short vowel in the relevant late clusters, producing forms such as *berstan* ‘burst’ where an earlier order would still show a broken vowel sequence.

Moving the rule before SC044 OEBreaking makes PGmc **bréstanq* ‘burst’ yield *†beorstan* rather than expected OE *berstan* ‘burst’. On this evidence, I take SC087 OERMetathesis to follow SC044 OEBreaking. Moving it later within the tested sequence alters no output.

The lexical evidence fixes the earlier relation but does not identify a corresponding later constraint. The sources treat r-metathesis as a late rearrangement after breaking without placing it immediately beside contraction.

70 Chapter 5. Old English orthography and the written surface

70.1 Historical interval

This short chapter stands apart from the derivational chapters that precede it. The changes of Chapters 1–3 are sound changes: they altered the spoken form of the language. The material treated here belongs instead to the written surface of Old English — scribal conventions that determined how the results of the completed phonological history were committed to parchment.

In the executable model these conventions apply after every phonological rule, at the very end of the cascade, because that is where they belong historically: a spelling practice can only render forms that the spoken language had already produced.

70.2 Scope

The one rule treated here is the West Saxon palatal-glide spelling (SC016), by which back vowels following word-initial [j] — spelled *g* — came to be written with a preceding front glide letter, as in *geoc* ‘yoke’ for spoken [jok] and *geogub* ‘youth’ for a form whose root vowel remained [u]. Ringe and Taylor state the modern assessment directly: the *eo* of *geoc* is a spelling convention, and the word was pronounced [jok] (Ringe and Taylor 2014, 5). Hogg reaches the same verdict for the back-vowel cases generally (Hogg 1992b, 113). The older handbooks — Campbell, Brunner, Bülbring, Luick — analysed the same spellings as rising diphthongs; the section below presents both views (Campbell 1959, 17, § 44; Brunner 1965, 64–65, § 92).

70.3 Sources

Ringe and Taylor provide the modern phonological interpretation (Ringe and Taylor 2014, 5). Campbell (Campbell 1959, 17, 64–67, §§ 44, 170–176), Brunner (Brunner 1965, 64–65, § 92), and Bülbring (Bülbring 1902, 120, §§ 298–299) document the distribution of the spellings; Hogg supplies the critical reassessment (Hogg 1992b, 113).

71 West Saxon palatal-glide spelling before back vowels

71.1 Historical discussion

West Saxon spellings such as *geoc* ‘yoke’, *geong* ‘young’, and *geogub* ‘youth’ write a front glide letter between a word-initial palatal and a following back vowel. Campbell describes the phenomenon as the development of rising diphthongs when “palatal glides developed before back vowels” and cites *geoc* directly (Campbell 1959, 17, §44); Brunner separates the *u*-cases (*geong*, *geogub*) from the *o*-cases (*gioc* ‘yoke’, *geoc*) (Brunner 1965, 64–65, §92.1); Bülbring likewise treats *iuguð* ‘youth’ and *iuc* under *ju* but derives *gioc*, *geoc* from West Germanic **jok* (Bülbring 1902, 120, §§298–299); and Luick groups all of these under his “schwebende Diphthonge” after palatal onsets (Luick 1914–1940, 158–59, §169).

The phonological interpretation of these spellings is disputed. The older handbook tradition — Campbell, Brunner, Bülbring, Luick — reads them as genuine rising diphthongs. The modern assessment is orthographic: Ringe and Taylor state flatly that *geoc* “is /jok/”, the digraph being a spelling convention that became universal after word-initial /j/ (Ringe and Taylor 2014, 5), and Hogg concludes that the back-vowel cases were “never anything more than an orthographic variation”, judging Campbell’s arguments to the contrary “insubstantial” (Hogg 1992b, 113; Campbell 1959, 66–67, §176). This model follows Ringe and Taylor and Hogg: the rule is a spelling convention applied to the finished phonology, and it therefore stands at the end of the derivation, in the written-surface stage of the cascade.

Its position also settles a relative chronology. The *o* of *geoc* ‘yoke’ is itself the product of Northwest Germanic u-lowering (SC017 PNWGMcULowering): Fulk lists *geoc* as a regular lowering example beside OIcel *ok* and OHG *joh* (Fulk 2018, 56, §4.3), and Campbell gives *geoc* among the regular *u* >

o words (Campbell 1959, 43, §115). The lowering therefore feeds the spelling: first **juk-* became **jok-* in Northwest Germanic, and only much later did West Saxon scribes write the result as *ġeoc*. Where lowering did not apply, as in *ġeogub* ‘youth’, whose root *u* was protected by the high vowel of the following syllable, the same convention wrote the retained *u* with the same digraph (Brunner 1965, 64–65, §92.1).

71.2 SC016. West Saxon palatal-glide spelling before back vowels (OEwsPalatalGlide)

```
define OEwsPalatalGlide [
  { *ó } -> { *éo } || .#. ġ _ ,
  { *ú } -> { *éo } || .#. ġ _ ,
  { *o } -> { *eo } || .#. ġ _ ,
  { *u } -> { *eo } || .#. ġ _
];
```

The rule rewrites a back vowel after word-initial *ġ* as the digraph spelling, covering both the lowered *o*-cases (*ġeoc* ‘yoke’) and the retained *u*-cases (*ġeogub* ‘youth’). Because it is a convention of the written language, it applies after every phonological change; in particular it follows SC017 PNWGmcULowering, which supplies the *o* of *ġeoc*. If the spelling rule were placed before *u*-lowering, the derivation would have to treat an Old English scribal practice as a Northwest Germanic sound change, an ordering that no source supports. The witnesses *ġeoc* and *ġeogub* between them fix both faces of the rule: one shows the convention applied to lowered *o*, the other to unlowered *u*. The handbook domain is broader (it also includes *a/ā/ō* contexts after word-initial palatals), but this executable rule is intentionally complete for the currently selected corpus witnesses rather than a maximal dialectal enumeration.
